#### Abstract

We study the problem of efficient online multiclass linear classification with bandit feedback, where all examples belong to one of $K$ classes and lie in the $d$-dimensional Euclidean space. Previous works have left open the challenge of designing efficient algorithms with finite mistake bounds when the data is linearly separable by a margin $\gamma$. In this work, we take a first step towards this problem. We consider two notions of linear separability, strong and weak.

1. Under the strong linear separability condition, we design an efficient algorithm that achieves a near-optimal mistake bound of $O\left(K / \gamma^{2}\right)$.
2. Under the more challenging weak linear separability condition, we design an efficient algorithm with a mistake bound of $\min \left(2^{\widetilde{O}\left(K \log ^{2}(1 / \gamma)\right)}, 2^{\widetilde{O}(\sqrt{1 / \gamma} \log K)}\right)^{1}$. Our algorithm is based on kernel Perceptron, which is inspired by the work of Klivans and Servedio [2008] on improperly learning intersection of halfspaces.

## 1 Introduction

We study the problem of Online Multiclass Linear Classification with Bandit Feedback [Kakade et al., 2008]. The problem can be viewed as a repeated game between a learner and an adversary. At each time step $t$, the adversary chooses a labeled example $\left(x_{t}, y_{t}\right)$ and reveals the feature vector $x_{t}$ to the learner. Upon receiving $x_{t}$, the learner makes a prediction $\widehat{y}_{t}$ and receives feedback. In contrast with the standard full-information setting, where the feedback given is the correct label $y_{t}$, here the feedback is only a binary indicator of whether the prediction was correct or not. The protocol of the problem is formally stated below.

The performance of the learner is measured by its cumulative number of mistakes $\sum_{t=1}^{T} z_{t}=\sum_{t=1}^{T} \mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]$, where $\mathbb{1}$ denotes the indicator function.

[^0]```
Protocol 1 Online Multiclass Linear Classification with Bandit Feedback
Require: Number of classes \(K\), number of rounds \(T\).
Require: Inner product space \((V,\langle\cdot, \cdot\rangle)\).
for \(t=1,2, \ldots, T\) do
    Adversary chooses example \(\left(x_{t}, y_{t}\right) \in V \times\{1,2, \ldots, K\}\) where \(x_{t}\) is revealed to the learner.
    Predict class label \(\widehat{y}_{t} \in\{1,2, \ldots, K\}\).
    Observe feedback \(z_{t}=\mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right] \in\{0,1\}\).
```

In this paper, we focus on the special case when the examples chosen by the adversary lie in $\mathbb{R}^{d}$ and are linearly separable with a margin. We introduce two notions of linear separability, weak and strong, formally stated in Definition 1. The standard notion of multiclass linear separability [Crammer and Singer, 2003] corresponds to the weak linear separability. For multiclass classification with $K$ classes, weak linear separability requires that all examples from the same class lie in an intersection of $K-1$ halfspaces and all other examples lie in the complement of the intersection of the halfspaces. Strong linear separability means that examples from each class are separated from the remaining examples by a single hyperplane.

In the full-information feedback setting, it is well known [Crammer and Singer, 2003] that if all examples have norm at most $R$ and are weakly linearly separable with a margin $\gamma$, then the Multiclass Perceptron algorithm makes at most $\left\lfloor 2(R / \gamma)^{2}\right\rfloor$ mistakes. It is also known that any (possibly randomized) algorithm must make $\frac{1}{2}\left\lfloor(R / \gamma)^{2}\right\rfloor$ mistakes in the worst case. The MUlticlass Perceptron achieves an information-theoretically optimal mistake bound, while being time and memory efficient. ${ }^{2}$

The bandit feedback setting, however, is much more challenging. For the case when the examples are strongly linearly separable, to the best of our knowledge, it is not known how to design an efficient algorithm with a finite mistake bound before our work. ${ }^{3}$ We design a simple and efficient algorithm (Algorithm 1) that makes at most $O\left(K(R / \gamma)^{2}\right)$ mistakes in expectation. Its memory complexity and per-round time complexity are both $O(d K)$. The algorithm can be viewed as running $K$ copies of the BinARY PERCEPTRON algorithm, one copy for each class. We prove that any (possibly randomized) algorithm must make $\Omega\left(K(R / \gamma)^{2}\right)$ mistakes in the worst case. The extra $O(K)$ multiplicative factor in the mistake bound, as compared to the full-information setting, is the price we pay for the bandit feedback, or more precisely, the lack of full-information feedback.

For the case when the examples are weakly linearly separable, it was open for a long time whether there exist efficient algorithms with finite mistake bound [Kakade et al., 2008, Beygelzimer et al., 2017]. Furthermore, Kakade et al. [2008] ask the question: Is there any algorithm with a finite mistake bound that has no explicit dependence on the dimensionality of the feature vectors? We answer both questions affirmatively by providing an efficient algorithm with finite dimensionless mistake bound (Algorithm 2). ${ }^{4}$

The strategy used in Algorithm 2 is to construct a non-linear feature mapping $\phi$ and associated positive definite kernel $k\left(x, x^{\prime}\right)$ that makes the examples strongly linearly separable in a higher-dimensional space. We then use the kernelized version of Algorithm 1 for the strongly separable case. The kernel $k\left(x, x^{\prime}\right)$ corresponding to the feature mapping $\phi$ has a simple explicit formula and can be computed in $O(d)$ time, making Algorithm 2 computationally efficient. For details on kernel methods see e.g. [Schölkopf and Smola, 2002] or [Shawe-Taylor and Cristianini, 2004].

The number of mistakes of the kernelized algorithm depends on the margin in the corresponding feature space. We analyze how the mapping $\phi$ transforms the margin parameter of weak separability in the original space $\mathbb{R}^{d}$ into a margin parameter of strong separability in the new feature space. This problem is related to the problem of learning intersection of halfspaces and has been studied previously by Klivans and Servedio [2008]. As a side result, we improve on the results of Klivans and Servedio [2008] by removing the dependency on the original dimension $d$.

The resulting kernelized algorithm runs in time polynomial in the original dimension of the feature vectors $d$, the number of classes $K$, and the number of rounds $T$. We prove that if the examples lie in the unit ball of $\mathbb{R}^{d}$ and are

[^1]weakly linearly separable with margin $\gamma$, Algorithm 2 makes at most $\min \left(2^{\widetilde{O}\left(K \log ^{2}(1 / \gamma)\right)}, 2^{\widetilde{O}(\sqrt{1 / \gamma} \log K)}\right)$ mistakes.
In Appendix G, we propose and analyze a very different algorithm for weakly linearly separable data. The algorithm is based on the obvious idea that two points that are close enough must have the same label.

Finally, we study two questions related to the computational and information-theoretic hardness of the problem. Any algorithm for the bandit setting collects information in the form of so called strongly labeled and weakly labeled examples. Strongly labeled examples are those for which we know the class label. Weakly labeled example is an example for which we know that class label can be anything except for one particular class. In Appendix H, we show that the offline problem of finding a multiclass linear classifier consistent with a set of strongly and weakly labeled examples is NP-hard. In Appendix I, we prove a lower bound on the number of mistakes of any algorithm that uses only strongly-labeled examples and ignores weakly labeled examples.

## 2 Related work

The problem of online bandit multiclass learning was initially formulated in the pioneering work of Auer and Long [1999] under the name of "weak reinforcement model". They showed that if all examples agree with some classifier from a prespecified hypothesis class $\mathcal{H}$, then the optimal mistake bound in the bandit setting can be upper bounded by the optimal mistake bound in the full information setting, times a factor of $(2.01+o(1)) K \ln K$. Long [2017] later improved the factor to $(1+o(1)) K \ln K$ and showed its near-optimality. Daniely and Helbertal [2013] extended the results to the setting where the performance of the algorithm is measured by its regret, i.e. the difference between the number of mistakes made by the algorithm and the number of mistakes made by the best classifier in $\mathcal{H}$ in hindsight. We remark that all algorithms developed in this context are computationally inefficient.

The linear classification version of this problem is initially studied by Kakade et al. [2008]. They proposed two computationally inefficient algorithms that work in the weakly linearly separable setting, one with a mistake bound of $O\left(K^{2} d \ln (d / \gamma)\right)$, the other with a mistake bound of $\widetilde{O}\left(\left(K^{2} / \gamma^{2}\right) \ln T\right)$. The latter result was later improved by Daniely and Helbertal [2013], which gives a computationally inefficient algorithm with a mistake upper bound of $\widetilde{O}\left(K / \gamma^{2}\right)$. In addition, Kakade et al. [2008] propose the BANDITRON algorithm, a computationally efficient algorithm that has a $O\left(T^{2 / 3}\right)$ regret against the multiclass hinge loss in the general setting, and has a $O(\sqrt{T})$ mistake bound in the $\gamma$-weakly linearly separable setting. In contrast to mild dependencies on the time horizon for mistake bounds of computationally inefficient algorithms, the polynomial dependence of BANDITRON's mistake bound on the time horizon is undesirable for problems with a long time horizon, in the weakly linearly separable setting. One key open question left by Kakade et al. [2008] is whether one can design computationally efficient algorithms that achieve mistake bounds that match or improve over those of inefficient algorithms. In this paper, we take a step towards answering this question, showing that efficient algorithms with mistake bounds quasipolynomial in $1 / \gamma$ (for constant $K$ ) and quasipolynomial in $K$ (for constant $\gamma$ ) can be obtained.

The general problem of linear bandit multiclass learning has received considerable attention [Abernethy and Rakhlin, 2009, Wang et al., 2010, Crammer and Gentile, 2013, Hazan and Kale, 2011, Beygelzimer et al., 2017, Foster et al., 2018]. Chen et al. [2014], Zhang et al. [2018] study online bandit multiclass boosting under bandit feedback, where one can view boosting as linear classification by treating each base hypothesis as a separate feature. In the weakly linearly separable setting, however, these algorithms can only guarantee a mistake bound of $O(\sqrt{T})$ at best.

The problem considered here is a special case of the contextual bandit problem [Auer et al., 2003, Langford and Zhang, 2008]. In this general problem, there is a hidden cost vector $c_{t}$ associated with every prediction in round $t$. Upon receiving $x_{t}$ and predicting $\widehat{y}_{t} \in\{1, \ldots, K\}$, the learner gets to observe the incurred cost $c_{t}\left(\widehat{y}_{t}\right)$. The goal of the learner is to minimize its regret with respect to the best predictor in some predefined policy class $\Pi$, given by $\sum_{t=1}^{T} c_{t}\left(\widehat{y}_{t}\right)-\min _{\pi \in \Pi} \sum_{t=1}^{T} c_{t}\left(\pi\left(x_{t}\right)\right)$. Bandit multiclass learning is a special case where the cost $c_{t}(i)$ is the classification error $\mathbb{1}\left[i \neq y_{t}\right]$ and the policy class is the set of linear classifiers $\left\{x \mapsto \operatorname{argmax}_{y}(W x)_{y}: W \in \mathbb{R}^{K \times d}\right\}$. There has been significant progress on the general contextual bandit problem assuming access to an optimization oracle that returns a policy in $\Pi$ with the smallest total cost on any given set of cost-sensitive examples [Dudík et al., 2011, Agarwal et al., 2014, Rakhlin and Sridharan, 2016, Syrgkanis et al., 2016a,b]. However, such an oracle abstracting efficient search through $\Pi$ is generally not available in our setting due to computational hardness results [Arora et al., 1997].

Recently, Foster and Krishnamurthy [2018] developed a rich theory of contextual bandits with surrogate losses, focusing on regrets of the form $\sum_{t=1}^{T} c_{t}\left(\widehat{y}_{t}\right)-\min _{f \in \mathcal{F}} \sum_{t=1}^{T} \frac{1}{K} \sum_{i=1}^{K} c_{t}(i) \phi\left(f_{i}\left(x_{t}\right)\right)$, where $\mathcal{F}$ contains score functions $f=\left(f_{1}, \ldots, f_{K}\right)$ such that $\sum_{i=1}^{K} f_{i}(\cdot) \equiv 0$, and $\phi(s)=\max \left(1-\frac{s}{\gamma}, 0\right)$ or $\min \left(1, \max \left(1-\frac{s}{\gamma}, 0\right)\right)$. On one hand, it gives information-theoretic regret upper bounds for various settings of $\mathcal{F}$. On the other hand, it gives an efficient algorithm with an $O(\sqrt{T})$ regret against the benchmark of $\mathcal{F}=\left\{x \mapsto W x: W \in \mathbb{R}^{K \times d}, \mathbb{1}^{T} W=0\right\}$. A direct application of this result to Online Bandit Multiclass Linear Classification gives an algorithm with $O(\sqrt{T})$ mistake bound in the strongly linearly separable case.

## 3 Notions of linear separability

We define two notions of linear separability for multiclass classification. The first notion is the standard notion of linear separability used in the proof of the mistake bound for the Multiclass Perceptron algorithm [see e.g. Crammer and Singer, 2003]. The second notion is stronger, i.e. more restrictive.

Definition 1 (Linear separability). Let $(V,\langle\cdot, \cdot\rangle)$ be an inner product space, $K$ be a positive integer, and $\gamma$ be a positive real number. We say that labeled examples $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right) \in V \times\{1,2, \ldots, K\}$ are

1. weakly linearly separable with a margin $\gamma$ if there exist vectors $w_{1}, w_{2}, \ldots, w_{K} \in V$ such that

$$
\begin{align*}
& \sum_{i=1}^{K}\left\|w_{i}\right\|^{2} \leq 1  \tag{1}\\
& \forall t \in\{1,2, \ldots, T\} \quad \forall i \in\{1,2, \ldots, K\} \backslash\left\{y_{t}\right\} \quad\left\langle x_{t}, w_{y_{t}}\right\rangle \geq\left\langle x_{t}, w_{i}\right\rangle+\gamma \tag{2}
\end{align*}
$$

2. strongly linearly separable with a margin $\gamma$ if there exist vectors $w_{1}, w_{2}, \ldots, w_{K} \in V$ such that

$$
\begin{align*}
& \sum_{i=1}^{K}\left\|w_{i}\right\|^{2} \leq 1  \tag{3}\\
& \forall t \in\{1,2, \ldots, T\} \quad\left\langle x_{t}, w_{y_{t}}\right\rangle \geq \gamma / 2  \tag{4}\\
& \forall t \in\{1,2, \ldots, T\} \quad \forall i \in\{1,2, \ldots, K\} \backslash\left\{y_{t}\right\}, \quad\left\langle x_{t}, w_{i}\right\rangle \leq-\gamma / 2 \tag{5}
\end{align*}
$$

The notion of strong linear separability has appeared in the literature; see e.g. [Chen et al., 2009]. Intuitively, strong linear separability means that, for each class $i$, the set of examples belonging to class $i$ and the set of examples belonging to the remaining $K-1$ classes are separated by a linear classifier $w_{i}$ with margin $\frac{\gamma}{2}$.

It is easy to see that if a set of labeled examples is strongly linearly separable with margin $\gamma$, then it is also weakly linearly separable with the same margin (or larger). Indeed, if $w_{1}, w_{2}, \ldots, w_{K} \in V$ satisfy (3), (4), (5) then they satisfy (1) and (2).

In the special case of $K=2$, if a set of labeled examples is weakly linearly separable with a margin $\gamma$, then it is also strongly linearly separable with the same margin. Indeed, if $w_{1}, w_{2}$ satisfy (1) and (2) then $w_{1}^{\prime}=\frac{w_{1}-w_{2}}{2}$, $w_{2}^{\prime}=\frac{w_{2}-w_{1}}{2}$ satisfy (3), (4), (5). Equation (3) follows from $\left\|w_{i}^{\prime}\right\|^{2} \leq\left(\frac{1}{2}\left\|w_{1}\right\|+\frac{1}{2}\left\|w_{2}\right\|\right)^{2} \leq \frac{1}{2}\left\|w_{1}\right\|^{2}+\frac{1}{2}\left\|w_{2}\right\|^{2} \leq \frac{1}{2}$ for $i=1,2$. Equations (4) and (5) follow from the fact that $w_{1}^{\prime}-w_{2}^{\prime}=w_{1}-w_{2}$.

However, for any $K \geq 3$ and any inner product space of dimension at least 2, there exists a set of labeled examples that is weakly linearly separable with a positive margin $\gamma$ but is not strongly linearly separable with any positive margin. Figure 1 shows one such set of labeled examples.

## 4 Algorithm for strongly linearly separable data

In this section, we consider the case when the examples are strongly linearly separable. We present an algorithm for this setting (Algorithm 1) and give an upper bound on its number of mistakes, stated as Theorem 2 below. The proof of the theorem can be found in Appendix B in the supplementary material.

Figure 1: A set of labeled examples in $\mathbb{R}^{2}$. The examples belong to $K=3$ classes colored white, gray and black respectively. Each class lies in a $120^{\circ}$ wedge. In other words, each class lies in an intersection of two halfspaces. While the examples are weakly linearly separable with a positive margin $\gamma$, they are not strongly linearly separable with any positive margin $\gamma$. For instance, there does not exist a linear separator that separates the examples belonging to the gray class from the examples belonging to the remaining two classes.

The idea behind Algorithm 1 is to use $K$ copies of the Binary Perceptron algorithm, one copy per class; see e.g. [Shalev-Shwartz, 2012, Section 3.3.1]. Upon seeing each example $x_{t}$, copy $i$ predicts whether or not $x_{t}$ belongs to class $i$. Multiclass predictions are done by evaluating all $K$ binary predictors and outputting any class with a positive prediction. If all binary predictions are negative, the algorithm chooses a prediction a prediction uniformly at random from $\{1, \ldots, K\}$.

Theorem 2 (Mistake upper bound). Let $(V,\langle\cdot, \cdot\rangle)$ be an inner product space, $K$ be a positive integer, $\gamma$ be a positive real number, $R$ be a non-negative real number. If the examples $\left(x_{1}, y_{1}\right), \ldots,\left(x_{T}, y_{T}\right) \in V \times\{1,2, \ldots, K\}$ are strongly linearly separable with margin $\gamma$ and $\left\|x_{1}\right\|,\left\|x_{2}\right\|, \ldots,\left\|x_{T}\right\| \leq R$ then the expected number of mistakes Algorithm 1 makes is at most $(K-1)\left\lfloor 4(R / \gamma)^{2}\right\rfloor$.

The upper bound $(K-1)\left\lfloor 4(R / \gamma)^{2}\right\rfloor$ on the expected number of mistakes of Algorithm 1 is optimal up to a constant factor, as long as the number of classes $K$ is at most $O\left((R / \gamma)^{2}\right)$. This lower bound is stated as Theorem 3 below. The proof of the theorem can be found in Appendix B in the supplementary material. Daniely and Helbertal [2013] provide a lower bound under the assumption of weak linear separability, which does not immediately imply a lower bound under the stronger notion.

Theorem 3 (Mistake lower bound). Let $\gamma$ be a positive real number, $R$ be a non-negative real number and let $K \leq(R / \gamma)^{2}$ be a positive integer. Any (possibly randomized) algorithm makes at least $((K-1) / 2)\left\lfloor(R / \gamma)^{2} / 4\right\rfloor$ mistakes in expectation on some sequence of labeled examples $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right) \in V \times\{1,2, \ldots, K\}$ for some inner product space $(V,\langle\cdot, \cdot\rangle)$ such that the examples are strongly linearly separable with margin $\gamma$ and satisfy $\left\|x_{1}\right\|,\left\|x_{2}\right\|, \ldots,\left\|x_{T}\right\| \leq R$.

Remark. If $\gamma \leq R$ then, irrespective of any other conditions on $K, R$, and $\gamma$, a trivial lower bound on the expected number of mistakes of any randomized algorithm is $(K-1) / 2$. To see this, note that the adversary can choose an example $\left(R e_{1}, y\right)$, where $e_{1}$ is some arbitrary unit vector in $V$ and $y$ is a label chosen uniformly from $\{1,2, \ldots, K\}$, and show this example $K$ times. The sequence of examples trivially satisfies the strong linear separability condition, and the $(K-1) / 2$ expected mistake lower bound follows from [Daniely and Helbertal, 2013, Claim 2].

Algorithm 1 can be extended to nonlinear classification using positive definite kernels (or kernels, for short), which are functions of the form $k: X \times X \rightarrow \mathbb{R}$ for some set $X$ such that the matrix $\left(k\left(x_{i}, x_{j}\right)\right)_{i, j=1}^{m}$ is a symmetric positive semidefinite for any positive integer $m$ and $x_{1}, x_{2}, \ldots, x_{m} \in X$ [Schölkopf and Smola, 2002, Definition 2.5]. ${ }^{5}$ As opposed to explicitly maintaining the weight vector for each class, the algorithm maintains the set of example-scalar

[^2]```

for \(t=1,2, \ldots, T\) do
    Observe feature vector \(x_{t} \in V\)
    Compute \(S_{t}=\left\{i: 1 \leq i \leq K,\left\langle w_{i}^{(t)}, x_{t}\right\rangle \geq 0\right\}\)
    if \(S_{t}=\emptyset\) then
        Predict \(\widehat{y}_{t} \sim \operatorname{Uniform}(\{1,2, \ldots, K\})\)
        Observe feedback \(z_{t}=\mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\)
        if \(z_{t}=1\) then
            Set \(w_{i}^{(t+1)}=w_{i}^{(t)}, \forall i \in\{1,2, \ldots, K\}\)
        else
            Set \(w_{i}^{(t+1)}=w_{i}^{(t)}, \forall i \in\{1,2, \ldots, K\} \backslash\left\{\widehat{y}_{t}\right\}\)
            Update \(w_{\widehat{y}_{t}}^{(t+1)}=w_{\widehat{y}_{t}}^{(t)}+x_{t}\)
    else
        Predict \(\widehat{y}_{t} \in S_{t}\) chosen arbitrarily
        Observe feedback \(z_{t}=\mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\)
        if \(z_{t}=1\) then
            Set \(w_{i}^{(t+1)}=w_{i}^{(t)}, \forall i \in\{1,2, \ldots, K\} \backslash\left\{\widehat{y}_{t}\right\}\)
            Update \(w_{\widehat{y}_{t}}^{(t+1)}=w_{\widehat{y}_{t}}^{(t)}-x_{t}\)
        else
            Set \(w_{i}^{(t+1)}=w_{i}^{(t)}, \forall i \in\{1,2, \ldots, K\}\)
```

pairs corresponding to the updates of the non-kernelized algorithm. As a direct consequence of Theorem 2 we get a mistake bound for the kernelized algorithm.

Theorem 4 (Mistake upper bound for kernelized algorithm). Let $X$ be a non-empty set, let $(V,\langle\cdot, \cdot\rangle)$ be an inner product space. Let $\phi: X \rightarrow V$ be a feature map and let $k: X \times X \rightarrow \mathbb{R}, k\left(x, x^{\prime}\right)=\left\langle\phi(x), \phi\left(x^{\prime}\right)\right\rangle$ be the associated positive definite kernel. Let $K$ be a positive integer, $\gamma$ be a positive real number, $R$ be a non-negative real number. If $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right) \in X \times\{1,2, \ldots, K\}$ are labeled examples such that:

1. the mapped examples $\left(\phi\left(x_{1}\right), y_{1}\right), \ldots,\left(\phi\left(x_{T}\right), y_{T}\right)$ are strongly linearly separable with margin $\gamma$,
2. $k\left(x_{1}, x_{1}\right), k\left(x_{2}, x_{2}\right), \ldots, k\left(x_{T}, x_{T}\right) \leq R^{2}$,
then the expected number of mistakes Algorithm 2 makes is at most $(K-1)\left\lfloor 4(R / \gamma)^{2}\right\rfloor$.

## 5 From weak separability to strong separability

In this section, we consider the case when the examples are weakly linearly separable. Throughout this section, we assume without loss of generality that all examples lie in the unit ball $\mathrm{B}(\mathbf{0}, 1) \subseteq \mathbb{R}^{d} .{ }^{6}$ Note that Algorithm 1 alone does not guarantee a finite mistake bound in this setting, as weak linear separability does not imply strong linear separability.

[^3]```
Algorithm 2 KERNELIZED BANDIT ALGORITHM
Require: Number of classes \(K\), number of rounds \(T\).
Require: Kernel function \(k(\cdot, \cdot)\).

    Observe feature vector \(x_{t}\).
    Compute
    \(S_{t}=\left\{i: 1 \leq i \leq K, \sum_{(x, y) \in J_{i}^{(t)}} y k\left(x, x_{t}\right) \geq 0\right\}\)
    if \(S_{t}=\emptyset\) then
        Predict \(\widehat{y}_{t} \sim \operatorname{Uniform}(\{1,2, \ldots, K\})\)
        Observe feedback \(z_{t}=\mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\)
        if \(z_{t}=1\) then
            Set \(J_{i}^{(t+1)}=J_{i}^{(t)}\) for all \(i \in\{1,2, \ldots, K\}\)
        else
            Set \(J_{i}^{(t+1)}=J_{i}^{(t)}, \forall i \in\{1,2, \ldots, K\} \backslash\left\{\widehat{y}_{t}\right\}\)
            Update \(J_{\widehat{y}_{t}}^{(t+1)}=J_{\widehat{y}_{t}}^{(t)} \cup\left\{\left(x_{t},+1\right)\right\}\)
    else
        Predict \(\widehat{y}_{t} \in S_{t}\) chosen arbitrarily
        Observe feedback \(z_{t}=\mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\)
        if \(z_{t}=1\) then
            Set \(J_{i}^{(t+1)}=J_{i}^{(t)}, \forall i \in\{1,2, \ldots, K\} \backslash\left\{\widehat{y}_{t}\right\}\)
            Update \(J_{\widehat{y}_{t}}^{(t+1)}=J_{\widehat{y}_{t}}^{(t)} \cup\left\{\left(x_{t},-1\right)\right\}\)
        else
            Set \(J_{i}^{(t+1)}=J_{i}^{(t)}\) for all \(i \in\{1,2, \ldots, K\}\)
```

We use a positive definite kernel function $k(\cdot, \cdot)$, namely rational kernel [Shalev-Shwartz et al., 2011], whose corresponding feature map $\phi(\cdot)$ transforms any sequence of weakly linearly separable examples to strongly linearly separable sequence of examples. Specifically, $\phi$ has the property that if a set of labeled examples in $\mathrm{B}(\mathbf{0}, 1)$ is weakly linearly separable with a margin $\gamma$, then after applying $\phi$ the examples become strongly linearly separable with a margin $\gamma^{\prime}$ and their squared norms are bounded by $2 .{ }^{7}$ The parameter $\gamma^{\prime}$ is a function of the old margin $\gamma$ and the number of classes $K$, and is specified in Theorem 5 below.

The rational kernel $k: \mathrm{B}(\mathbf{0}, 1) \times \mathrm{B}(\mathbf{0}, 1) \rightarrow \mathbb{R}$ is defined as

$$
\begin{equation*}
k\left(x, x^{\prime}\right)=\frac{1}{1-\frac{1}{2}\left\langle x, x^{\prime}\right\rangle_{\mathbb{R}^{d}}} . \tag{6}
\end{equation*}
$$

Note that $k\left(x, x^{\prime}\right)$ can be evaluated in $O(d)$ time.
Consider the classical real separable Hilbert space $\ell_{2}=\left\{x \in \mathbb{R}^{\infty}: \sum_{i=1}^{\infty} x_{i}^{2}<+\infty\right\}$ equipped with the standard inner product $\left\langle x, x^{\prime}\right\rangle_{\ell_{2}}=\sum_{i=1}^{\infty} x_{i} x_{i}^{\prime}$. If we index the coordinates of $\ell_{2}$ by $d$-tuples $\left(\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}\right)$ of non-negative integers, the feature map that corresponds to $k$ is $\phi: \mathrm{B}(\mathbf{0}, 1) \rightarrow \ell_{2}$,

$$
\begin{equation*}
\left(\phi\left(x_{1}, x_{2}, \ldots, x_{d}\right)\right)_{\left(\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}\right)}=x_{1}^{\alpha_{1}} x_{2}^{\alpha_{2}} \ldots x_{d}^{\alpha_{d}} \cdot \sqrt{2^{-\left(\alpha_{1}+\alpha_{2}+\cdots+\alpha_{d}\right)}\binom{\alpha_{1}+\alpha_{2}+\cdots+\alpha_{d}}{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}} \tag{7}
\end{equation*}
$$

where $\binom{\alpha_{1}+\alpha_{2}+\cdots+\alpha_{d}}{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}=\frac{\left(\alpha_{1}+\alpha_{2}+\cdots+\alpha_{d}\right)!}{\alpha_{1}!\alpha_{2}!\ldots \alpha_{d}!}$ is the multinomial coefficient. It can be easily checked that

$$
k\left(x, x^{\prime}\right)=\left\langle\phi(x), \phi\left(x^{\prime}\right)\right\rangle_{\ell_{2}} .
$$

[^4]The last equality together with the formula for $k$ implies that $k(x, x)<+\infty$ for any $x$ in $\mathrm{B}(\mathbf{0}, 1)$ and thus in particular implies that $\phi(x)$ indeed lies in $\ell_{2}$.

The following theorem is our main technical result in this section. We defer its proof to Section 5.1.
Theorem 5 (Margin transformation). Let $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right)$ in $\mathrm{B}(\mathbf{0}, 1) \times\{1,2, \ldots, K\}$ be a sequence of labeled examples that is weakly linearly separable with margin $\gamma>0$. Let $\phi$ be as defined in equation (7) and let

$$
\gamma_{1}=\frac{\left[376\left\lceil\log _{2}(2 K-2)\right\rceil \cdot\left[\sqrt{\frac{2}{\gamma}}\right\rceil\right]^{\frac{-\left\lceil\log _{2}(2 K-2) 7 \cdot\lceil\sqrt{2 / \gamma}\rceil\right.}{2}}}{2 \sqrt{K}}, \gamma_{2}=\frac{\left(2^{s+1} r(K-1)(4 s+2)\right)^{-(s+1 / 2) r(K-1)}}{4 \sqrt{K}(4 K-5) 2^{K-1}},
$$

where $r=2\left\lceil\frac{1}{4} \log _{2}(4 K-3)\right\rceil+1$ and $s=\left\lceil\log _{2}(2 / \gamma)\right\rceil$. Then, the sequence of labeled examples transformed by $\phi$, namely $\left(\phi\left(x_{1}\right), y_{1}\right),\left(\phi\left(x_{2}\right), y_{2}\right), \ldots,\left(\phi\left(x_{T}\right), y_{T}\right)$, is strongly linearly separable with margin $\gamma^{\prime}=\max \left\{\gamma_{1}, \gamma_{2}\right\}$. In addition, for all $t$ in $\{1, \ldots, T\}, k\left(x_{t}, x_{t}\right) \leq 2$.

Using this theorem we derive a mistake bound for Algorithm 2 with kernel (6) under the weak linear separability assumption.

Corollary 6 (Mistake upper bound). Let $K$ be a positive integer and let $\gamma$ be a positive real number. If $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right) \in$ $\mathrm{B}(0,1) \times\{1,2, \ldots, K\}$ is a sequence of weakly separable labeled examples with margin $\gamma>0$, then the expected number of mistakes made by Algorithm 2 with kernel $k\left(x, x^{\prime}\right)$ defined by (6) is at most $\min \left(2^{\widetilde{O}\left(K \log ^{2}(1 / \gamma)\right)}, 2^{\widetilde{O}(\sqrt{1 / \gamma} \log K)}\right)$.

This corollary follows directly from Theorems 4 and 5.

### 5.1 Proof of Theorem 5

Overview. The idea behind the construction and analysis of the mapping $\phi$ is polynomial approximation. Specifically, we construct $K$ multivariate polynomials $p_{1}, p_{2}, \ldots, p_{K}$ such that

$$
\begin{align*}
& \forall t \in\{1,2, \ldots, T\}, \quad p_{y_{t}}\left(x_{t}\right) \geq \frac{\gamma^{\prime}}{2}  \tag{8}\\
& \forall t \in\{1,2, \ldots, T\} \quad \forall i \in\{1,2, \ldots, K\} \backslash\left\{y_{t}\right\}, \quad p_{i}\left(x_{t}\right) \leq-\frac{\gamma^{\prime}}{2} \tag{9}
\end{align*}
$$

We then show (Lemma 9) that each polynomial $p_{i}$ can be expressed as $\left\langle c_{i}, \phi(x)\right\rangle_{\ell_{2}}$ for some $c_{i} \in \ell_{2}$. This immediately implies that that the examples $\left(\phi\left(x_{1}\right), y_{1}\right), \ldots,\left(\phi\left(x_{T}\right), y_{T}\right)$ are strongly linearly separable with a positive margin.

The conditions (8) and (9) are equivalent to that

$$
\begin{gather*}
\forall t \in\{1,2, \ldots, T\}, y_{t}=i \quad \Rightarrow \quad p_{i}\left(x_{t}\right) \geq \frac{\gamma^{\prime}}{2}  \tag{10}\\
\forall t \in\{1,2, \ldots, T\}, y_{t} \neq i \quad \Rightarrow \quad p_{i}\left(x_{t}\right) \leq-\frac{\gamma^{\prime}}{2} \tag{11}
\end{gather*}
$$

hold for all $i \in\{1,2, \ldots, K\}$. We can thus fix $i$ and focus on construction of one particular polynomial $p_{i}$.
Since examples $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right)$ are weakly linearly separable, all examples from class $i$ lie in

$$
R_{i}^{+}=\bigcap_{j \in\{1,2, \ldots, K\} \backslash\{i\}}\left\{x \in \mathrm{~B}(\mathbf{0}, 1):\left\langle w_{i}^{*}-w_{j}^{*}, x\right\rangle \geq \gamma\right\}
$$

and all examples from the remaining classes lie in

$$
R_{i}^{-}=\bigcup_{j \in\{1,2, \ldots, K\} \backslash\{i\}}\left\{x \in \mathrm{~B}(\mathbf{0}, 1):\left\langle w_{i}^{*}-w_{j}^{*}, x\right\rangle \leq-\gamma\right\}
$$

Therefore, to satisfy conditions (10) and (11), it suffices to construct $p_{i}$ such that

$$
\begin{array}{lll}
x \in R_{i}^{+} & \Longrightarrow & p_{i}(x) \geq \frac{\gamma^{\prime}}{2} \\
x \in R_{i}^{-} & \Longrightarrow & p_{i}(x) \leq-\frac{\gamma^{\prime}}{2} \tag{13}
\end{array}
$$

According to the well known Stone-Weierstrass theorem [see e.g. Davidson and Donsig, 2010, Section 10.10], on a compact set, multivariate polynomials uniformly approximate any continuous function. Roughly speaking, the conditions (12) and (13) mean that $p_{i}$ approximates on $\mathrm{B}(\mathbf{0}, 1)$ a scalar multiple of the indicator function of the intersection of $K-1$ halfspaces $\bigcap_{j \in\{1,2, \ldots, K\} \backslash\{i\}}\left\{x:\left\langle w_{i}^{*}-w_{j}^{*}, x\right\rangle \geq 0\right\}$ while within margin $\gamma$ along the decision boundary, the polynomial is allowed to attain arbitrary values. It is thus clear such a polynomial exists.

We give two explicit constructions for such polynomial in Theorems 7 and 8. Our constructions are based on Klivans and Servedio [2008] which in turn uses the constructions from Beigel et al. [1995]. More importantly, the theorems quantify certain parameters of the polynomial, which allows us to upper bound the transformed margin $\gamma^{\prime}$.

Before we state the theorems, recall that a polynomial of $d$ variables is a function $p: \mathbb{R}^{d} \rightarrow \mathbb{R}$ of the form

$$
p(x)=p\left(x_{1}, x_{2}, \ldots, x_{d}\right)=\sum_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}} c_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}} x_{1}^{\alpha_{1}} x_{2}^{\alpha_{2}} \ldots x_{d}^{\alpha_{d}}
$$

where the sum ranges over a finite set of $d$-tuples $\left(\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}\right)$ of non-negative integers and $c_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}$ 's are real coefficients. The degree of a polynomial $p$, denoted by $\operatorname{deg}(p)$, is the largest value of $\alpha_{1}+\alpha_{2}+\cdots+\alpha_{d}$ for which the coefficient $c_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}$ is non-zero. Following the terminology of Klivans and Servedio [2008], the norm of a polynomial $p$ is defined as

$$
\|p\|=\sqrt{\sum_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}\left(c_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}\right)^{2}}
$$

It is easy see that this is indeed a norm, since we can interpret it as the Euclidean norm of the vector of the coefficients of the polynomial.

Theorem 7 (Polynomial approximation of intersection of halfspaces I). Let $v_{1}, v_{2}, \ldots, v_{m} \in \mathbb{R}^{d}$ be vectors such that $\left\|v_{1}\right\|,\left\|v_{2}\right\|, \ldots,\left\|v_{m}\right\| \leq 1$. Let $\gamma \in(0,1)$. There exists a multivariate polynomial $p: \mathbb{R}^{d} \rightarrow \mathbb{R}$ such that

1. $p(x) \geq 1 / 2$ for all $x \in R^{+}=\bigcap_{i=1}^{m}\left\{x \in \mathrm{~B}(\mathbf{0}, 1):\left\langle v_{i}, x\right\rangle \geq \gamma\right\}$,
2. $p(x) \leq-1 / 2$ for all $x \in R^{-}=\bigcup_{i=1}^{m}\left\{x \in \mathrm{~B}(\mathbf{0}, 1):\left\langle v_{i}, x\right\rangle \leq-\gamma\right\}$,
3. $\operatorname{deg}(p)=\left\lceil\log _{2}(2 m)\right\rceil \cdot\lceil\sqrt{1 / \gamma}\rceil$,
4. $\|p\| \leq\left[188\left\lceil\log _{2}(2 m)\right\rceil \cdot[\sqrt{1 / \gamma}\rceil\right]^{\frac{\left\lceil\log _{2}(2 m)\right\rceil \cdot\lceil\sqrt{1 / \gamma}\rceil}{2}}$.

Theorem 8 (Polynomial approximation of intersection of halfspaces II). Let $v_{1}, v_{2}, \ldots, v_{m} \in \mathbb{R}^{d}$ be vectors such that $\left\|v_{1}\right\|,\left\|v_{2}\right\|, \ldots,\left\|v_{m}\right\| \leq 1$. Let $\gamma \in(0,1)$. Define

$$
r=2\left\lceil\frac{1}{4} \log _{2}(4 m+1)\right\rceil+1 \quad \text { and } \quad s=\left\lceil\log _{2}(1 / \gamma)\right\rceil .
$$

Then, there exists a multivariate polynomial $p: \mathbb{R}^{d} \rightarrow \mathbb{R}$ such that

Figure 2: The figure shows the two regions $R^{+}$and $R^{-}$used in parts 1 and 2 of Theorems 7 and 8 for the case $m=d=2$ and a particular choice of vectors $v_{1}, v_{2}$ and margin parameter $\gamma$. The separating hyperplanes $\left\langle v_{1}, x\right\rangle=0$ and $\left\langle v_{2}, x\right\rangle=0$ are shown as dashed lines.

1. $p(x) \geq 1 / 2$ for all $x \in R^{+}=\bigcap_{i=1}^{m}\left\{x \in \mathrm{~B}(\mathbf{0}, 1):\left\langle v_{i}, x\right\rangle \geq \gamma\right\}$,
2. $p(x) \leq-1 / 2$ for all $x \in R^{-}=\bigcup_{i=1}^{m}\left\{x \in \mathrm{~B}(\mathbf{0}, 1):\left\langle v_{i}, x\right\rangle \leq-\gamma\right\}$,
3. $\operatorname{deg}(p) \leq(2 s+1) r m$,
4. $\|p\| \leq(4 m-1) 2^{m} \cdot\left(2^{s} r m(4 s+2)\right)^{(s+1 / 2) r m}$.

The proofs of the theorems are in Appendix D. The geometric interpretation of the two regions $R^{+}$and $R^{-}$ in the theorems is explained in Figure 2. Similar but weaker results were proved by Klivans and Servedio [2008]. Specifically, our bounds in parts $1,2,3,4$ of Theorems 7 and 8 are independent of the dimension $d$.

The following lemma establishes a correspondence between any multivariate polynomial in $\mathbb{R}^{d}$ and an element in $\ell_{2}$, and gives an upper bound on its norm. Its proof follows from simple algebra, which we defer to Appendix $\mathbf{C}$.

Lemma 9 (Norm bound). Let $p: \mathbb{R}^{d} \rightarrow \mathbb{R}$ be a multivariate polynomial. There exists $c \in \ell_{2}$ such that $p(x)=$ $\langle c, \phi(x)\rangle_{\ell_{2}}$ and $\|c\|_{\ell_{2}} \leq 2^{\operatorname{deg}(p) / 2}\|p\|$.

Using the lemma and the polynomial approximation theorems, we can prove that the mapping $\phi$ maps any set of weakly linearly separable examples to a strongly linearly separable set of examples. Due to space constraints, we defer the full proof of Theorem 5 to Appendix E.

## 6 Experiments

In this section, we provide an empirical evaluation on our algorithms, verifying their effectiveness on linearly separable datasets. We generated strongly and weakly linearly separable datasets with $K=3$ classes in $\mathbb{R}^{3}$ i.i.d. from two data distributions. Figures 3 a and 3 b show visualizations of the two datasets, along with detailed descriptions of the distributions.

We implemented Algorithm 1, Algorithm 2 with rational kernel (6) and used implementation of BANDITRON algorithm by Orabona [2009]. ${ }^{8}$ We evaluated these algorithms on the two datasets. BANDITRON has an exploration rate parameter, for which we tried values $0.02,0.01,0.005,0.002,0.001,0.0005$. Since all three algorithms are randomized, we run each algorithm 20 times. The average cumulative number of mistakes up to round $t$ as a function of $t$ are shown in Figures 4 and 5.

We can see that there is a tradeoff in the setting of the exploration rate for Banditron. With large exploration parameter, BANDITRON suffers from over-exploration, whereas with small exploration parameter, its model cannot

[^5]

Figure 3: Strongly and weakly linearly separable datasets in $\mathbb{R}^{3}$ with $K=3$ classes and $T=5 \times 10^{6}$ examples. Here we show projections of the examples onto their first two coordinates, which lie in the ball of radius $1 / \sqrt{2}$ centered at the origin. The third coordinate is $1 / \sqrt{2}$ for all examples. Class 1 is depicted red. Classes 2 and 3 are depicted green and blue, respectively. $80 \%$ of the examples belong to class $1,10 \%$ belong to class 2 and $10 \%$ belong to class 3. Class 1 lies in the angle interval [ $-15^{\circ}, 15^{\circ}$, while classes 2 and 3 lie in the angle intervals $\left[15^{\circ}, 180^{\circ}\right]$ and $\left[-180^{\circ},-15^{\circ}\right]$ respectively. The examples are strongly and weakly linearly separable with a margin of $\gamma=0.05$, respectively. (Examples lying within margin $\gamma$ of the linear separators were rejected during sampling.)
be updated quickly enough. As expected, Algorithm 1 has a small number of mistakes in the strongly linearly separable setting, while having a large number of mistakes in the weakly linearly separable setting, due to the limited representation power of linear classifiers. In contrast, Algorithm 2 with rational kernel has a small number of mistakes in both settings, exhibiting strong adaptivity guarantees. Appendix F shows the decision boundaries that each of the algorithms learns by the end of the last round.

Figure 4: Average cumulative number of mistakes of various algorithms versus the number of rounds for the strongly linearly separable dataset of Figure 3a.

Figure 5: Average cumulative number of mistakes of various algorithms versus the number of rounds for the weakly linearly separable dataset of Figure 3b.

## A Multiclass Perceptron

Multiclass Perceptron is an algorithm for Online Multiclass Classification. Both the protocol for the problem and the algorithm are stated below. The algorithm assumes that the feature vectors come from an inner product space $(V,\langle\cdot, \cdot\rangle)$.

Two results are folklore. The first result is Theorem 10 which states that if examples are linearly separable with margin $\gamma$ and examples have norm at most $R$ then the algorithm makes at most $\left\lfloor 2(R / \gamma)^{2}\right\rfloor$ mistakes. The second result is Theorem 11 which states that under the same assumptions as in Theorem 11 any deterministic algorithm for Online Multiclass Classification must make at least $\left\lfloor(R / \gamma)^{2}\right\rfloor$ mistakes in the worst case.

Protocol 2 OnLINE MULTICLASS CLASSIFICATION
Require: Number of classes $K$, number of rounds $T$.
Require: Inner product space $(V,\langle\cdot, \cdot\rangle)$.
for $t=1,2, \ldots, T$ do
Adversary chooses example $\left(x_{t}, y_{t}\right) \in V \times\{1,2, \ldots, K\}$, where $x_{t}$ is revealed to the learner.
Predict class label $\widehat{y}_{t} \in\{1,2, \ldots, K\}$.
Observe feedback $y_{t}$.

```
Algorithm 3 MULTICLASS PERCEPTRON
Require: Number of classes \(K\), number of rounds \(T\).
Require: Inner product space \((V,\langle\cdot, \cdot\rangle)\).
Initialize \(w_{1}^{(1)}=w_{2}^{(1)}=\cdots=w_{K}^{(1)}=0\)
for \(t=1,2, \ldots, T\) do
    Observe feature vector \(x_{t} \in V\)
    Predict \(\widehat{y}_{t}=\operatorname{argmax}_{i \in\{1,2, \ldots, K\}}\left\langle w_{t}^{(i)}, x_{t}\right\rangle\)
    Observe \(y_{t} \in\{1,2, \ldots, K\}\)
    if \(\widehat{y}_{t} \neq y_{t}\) then
            Set \(w_{i}^{(t+1)}=w_{i}^{(t)}\)
            for all \(i \in\{1,2, \ldots, K\} \backslash\left\{y_{t}, \widehat{y}_{t}\right\}\)
            Update \(w_{y_{t}}^{(t+1)}=w_{y_{t}}^{(t)}+x_{t}\)
            Update \(w_{\widehat{y}_{t}}^{(t+1)}=w_{\widehat{y}_{t}}^{(t)}-x_{t}\)
    else
            Set \(w_{i}^{(t+1)}=w_{i}^{(t)}\) for all \(i \in\{1,2, \ldots, K\}\)
```

Theorem 10 (Mistake upper bound Crammer and Singer [2003]). Let $(V,\langle\cdot, \cdot\rangle)$ be an inner product space, let $K$ be a positive integer, let $\gamma$ be a positive real number and let $R$ be a non-negative real number. If $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right)$ is a sequence of labeled examples in $V \times\{1,2, \ldots, K\}$ that are weakly linearly separable with margin $\gamma$ and $\left\|x_{1}\right\|,\left\|x_{2}\right\|, \ldots,\left\|x_{T}\right\| \leq R$ then Multiclass Perceptron algorithm makes at most $\left\lfloor 2(R / \gamma)^{2}\right\rfloor$ mistakes.
Proof. Let $M=\sum_{t=1}^{T} \mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]$ be the number of mistakes the algorithm makes. Since the $K$-tuple $\left(w_{1}^{(t)}, w_{2}^{(t)}, \ldots, w_{K}^{(t)}\right)$ changes only if a mistake is made, we can upper bound $\sum_{i=1}^{K}\left\|w_{i}^{(t)}\right\|^{2}$ in terms of number of mistakes. If a mistake
happens in round $t$ then

$$
\begin{aligned}
\sum_{i=1}^{K}\left\|w_{i}^{(t+1)}\right\|^{2} & =\left(\sum_{i \in\{1,2, \ldots, K\} \backslash\left\{y_{t}, \widehat{y}_{t}\right\}}\left\|w_{i}^{(t)}\right\|^{2}\right)+\left\|w_{y_{t}}^{(t)}+x_{t}\right\|^{2}+\left\|w_{\widehat{y}_{t}}^{(t)}-x_{t}\right\|^{2} \\
& =\left(\sum_{i \in\{1,2, \ldots, K\} \backslash\left\{y_{t}, \widehat{y}_{t}\right\}}\left\|w_{i}^{(t)}\right\|^{2}\right)+\left\|w_{y_{t}}^{(t)}\right\|^{2}+\left\|w_{\widehat{y}_{t}}^{(t)}\right\|^{2}+2\left\|x_{t}\right\|^{2}+2\left\langle w_{y_{t}}^{(t)}-w_{\widehat{y}_{t}}^{(t)}, x_{t}\right\rangle \\
& =\left(\sum_{i=1}^{K}\left\|w_{i}^{(t)}\right\|^{2}\right)+2\left\|x_{t}\right\|^{2}+2\left\langle w_{y_{t}}^{(t)}-w_{\widehat{y}_{t}}^{(t)}, x_{t}\right\rangle \\
& \leq\left(\sum_{i=1}^{K}\left\|w_{i}^{(t)}\right\|^{2}\right)+2\left\|x_{t}\right\|^{2} \\
& \leq\left(\sum_{i=1}^{K}\left\|w_{i}^{(t)}\right\|^{2}\right)+2 R^{2} .
\end{aligned}
$$

So each time a mistake happens, $\sum_{i=1}^{K}\left\|w_{i}^{(t)}\right\|^{2}$ increases by at most $2 R^{2}$. Thus,

$$
\begin{equation*}
\sum_{i=1}^{K}\left\|w_{i}^{(T+1)}\right\|^{2} \leq 2 R^{2} M \tag{14}
\end{equation*}
$$

Let $w_{1}^{*}, w_{2}^{*}, \ldots, w_{K}^{*} \in V$ be vectors satisfying (1) and (2). We lower bound $\sum_{i=1}^{K}\left\langle w_{i}^{*}, w_{i}^{(t)}\right\rangle$. This quantity changes only when a mistakes happens. If mistake happens in round $t$, we have

$$
\begin{aligned}
\sum_{i=1}^{K}\left\langle w_{i}^{*}, w_{i}^{(t+1)}\right\rangle & =\left(\sum_{i \in\{1,2, \ldots, K\} \backslash\left\{y_{t}, \widehat{y}_{t}\right\}}\left\langle w_{i}^{*}, w_{i}^{(t)}\right\rangle\right)+\left\langle w_{y_{t}}^{*}, w_{y_{t}}^{(t)}+x_{t}\right\rangle+\left\langle w_{\widehat{y}_{t}}^{*}, w_{\widehat{y}_{t}}^{(t)}-x_{t}\right\rangle \\
& =\left(\sum_{i=1}^{K}\left\langle w_{i}^{*}, w_{i}^{(t)}\right\rangle\right)+\left\langle w_{y_{t}}^{*}-w_{\widehat{y}_{t}}^{*}, x_{t}\right\rangle \\
& \geq\left(\sum_{i=1}^{K}\left\langle w_{i}^{*}, w_{i}^{(t)}\right\rangle\right)+\gamma .
\end{aligned}
$$

Thus, after $M$ mistakes,

$$
\sum_{i=1}^{K}\left\langle w_{i}^{*}, w_{i}^{(T+1)}\right\rangle \geq \gamma M
$$

We upper bound the left hand side by using Cauchy-Schwartz inequality twice and the condition (1) on $w_{1}^{*}, w_{2}^{*}, \ldots, w_{K}^{*}$.

We have

$$
\begin{aligned}
\sum_{i=1}^{K}\left\langle w_{i}^{*}, w_{i}^{(T+1)}\right\rangle & \leq \sum_{i=1}^{K}\left\|w_{i}^{*}\right\| \cdot\left\|w_{i}^{(T+1)}\right\| \\
& \leq \sqrt{\sum_{i=1}^{K}\left\|w_{i}^{*}\right\|^{2}} \sqrt{\sum_{i=1}^{K}\left\|w_{i}^{(T+1)}\right\|^{2}} \\
& \leq \sqrt{\sum_{i=1}^{K}\left\|w_{i}^{(T+1)}\right\|^{2}}
\end{aligned}
$$

Combining the above inequality with Equations (14) and (A), we get

$$
(\gamma M)^{2} \leq \sum_{i=1}^{K}\left\|w_{i}^{(T+1)}\right\|^{2} \leq 2 R^{2} M
$$

We conclude that $M \leq 2(R / \gamma)^{2}$. Since $M$ is an integer, $M \leq\left\lfloor 2(R / \gamma)^{2}\right\rfloor$.
Theorem 11 (Mistake lower bound). Let $K$ be a positive integer, let $\gamma$ be a positive real number and let $R$ be a nonnegative real number. For any (possibly randomized) algorithm $\mathcal{A}$ for the Online Multiclass Classification problem there exists an inner product space $(V,\langle\cdot, \cdot\rangle)$, a non-negative integer $T$ and a sequence of labeled examples $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right)$ examples in $V \times\{1,2, \ldots, K\}$ that are weakly linearly separable with margin $\gamma$, the norms satisfy $\left\|x_{1}\right\|,\left\|x_{2}\right\|, \ldots,\left\|x_{T}\right\| \leq R$ and the algorithm makes at least $\frac{1}{2}\left\lfloor(R / \gamma)^{2}\right\rfloor$ mistakes.

Proof. Let $T=\left\lfloor(R / \gamma)^{2}\right\rfloor, V=\mathbb{R}^{T}$, and for all $t$ in $\{1, \ldots, T\}$, define instance $x_{t}=R e_{t}$ where $e_{t}$ is $t$-th element of the standard orthonormal basis of $\mathbb{R}^{T}$. Let labels $y_{1}, \ldots, y_{T}$ be chosen i.i.d uniformly at random from $\{1,2, \ldots, K\}$ and independently of any randomness used by the algorithm $\mathcal{A}$.

We first show that the set of examples $\left(x_{1}, y_{1}\right), \ldots,\left(x_{T}, y_{T}\right)$ we have constructed is weakly linearly separable with margin $\gamma$. To prove that, we demonstrate vectors $w_{1}, w_{2}, \ldots, w_{K}$ satisfying conditions (1) and (2). We define

$$
w_{i}=\frac{\gamma}{R} \sum_{\substack{t: 1 \leq t \leq T \\ y_{t}=i}} e_{t} \quad \text { for } i=1,2, \ldots, K
$$

Let $a_{i}=\left|\left\{t: 1 \leq t \leq T, y_{t}=i\right\}\right|$ be the number of occurrences of label $i$. It is easy to see that

$$
\left\|w_{i}\right\|^{2}=\frac{\gamma^{2}}{R^{2}} \sum_{\substack{t: 1 \leq t \leq T \\ y_{t}=i}}\left\|e_{t}\right\|^{2}=\frac{a_{i} \gamma^{2}}{R^{2}} \quad \text { for } i=1,2, \ldots, K
$$

Since $\sum_{i=1}^{K} a_{i}=T, \sum_{i=1}^{K}\left\|w_{i}\right\|^{2}=T \cdot \frac{\gamma^{2}}{R^{2}} \leq 1$, i.e. the condition (1) holds. To verify condition (2) consider any labeled example $\left(x_{t}, y_{t}\right)$. Then, for any $i$ in $\{1, \ldots, K\}$, by the definition of $w_{i}$, we have

$$
\begin{aligned}
\left\langle w_{i}, x_{t}\right\rangle & =\frac{\gamma}{R} \sum_{\substack{s: 1 \leq s \leq T \\
y_{s}=i}}\left\langle e_{s}, R e_{t}\right\rangle \\
& =\gamma \cdot \sum_{\substack{s: 1 \leq s \leq T \\
y_{s}=i}} \mathbb{1}[s=t] \\
& =\gamma \cdot \mathbb{1}\left[y_{t}=i\right]
\end{aligned}
$$

Therefore, if $i=y_{t},\left\langle w_{i}, x_{t}\right\rangle=\gamma$; otherwise $i \neq y_{t}$, in which case $\left\langle w_{i}, x_{t}\right\rangle=0$. Hence, condition (2) holds.

We now give a lower bound on the number of mistakes $\mathcal{A}$ makes. As $y_{t}$ is chosen uniformly from $\{1,2, \ldots, K\}$, independently from $\mathcal{A}$ 's randomization and the first $t-1$ examples,

$$
\mathbf{E}\left[\mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\right] \geq 1-\frac{1}{K} \geq \frac{1}{2}
$$

Summing over all $t$ in $\{1, \ldots, T\}$, we conclude that

$$
\mathbf{E}\left[\sum_{t=1}^{T} \mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\right] \geq \frac{T}{2}=\frac{1}{2}\left\lfloor(R / \gamma)^{2}\right\rfloor
$$

which completes the proof.

## B Proofs of Theorems 2 and 3

Proof of Theorem 2. Let $M=\sum_{t=1}^{T} z_{t}$ be the number of mistakes Algorithm 1 makes. Let $A=\sum_{t=1}^{T} \mathbb{1}\left[S_{t} \neq \emptyset\right] z_{t}$ be the number of mistakes in the rounds when $S_{t} \neq \emptyset$, i.e. the number of rounds line 18 is executed. In addition, let $B=\sum_{t=1}^{T} \mathbb{1}\left[S_{t}=\emptyset\right] z_{t}$ be the number of mistakes in the rounds when $S_{t}=\emptyset$. It can be easily seen that $M=A+B$.

Let $C=\sum_{t=1}^{T} \mathbb{1}\left[S_{t}=\emptyset\right]\left(1-z_{t}\right)$ be the number of rounds line 12 gets executed. Let $U=\sum_{t=1}^{T}\left(\mathbb{1}\left[S_{t} \neq \emptyset\right] z_{t}+\right.$ $\left.\mathbb{1}\left[S_{t}=\emptyset\right]\left(1-z_{t}\right)\right)$ be the number of rounds line 12 or 18 gets executed. In other words, $U$ is the number of times the $K$-tuple of vectors $\left(w_{1}^{(t)}, w_{2}^{(t)}, \ldots, w_{K}^{(t)}\right)$ gets updated. It can be easily seen that $U=A+C$.

The key observation is that $\mathbf{E}[B]=(K-1) \mathbf{E}[C]$. To see this, note that if $S_{t}=\emptyset$, there is $1 / K$ probability that the algorithm guesses the correct label $\left(z_{t}=0\right)$ and with probability $(K-1) / K$ algorithm's guess is incorrect $\left(z_{t}=1\right)$. Therefore,

$$
\begin{gathered}
\mathbf{E}\left[z_{t} \mid S_{t}=\emptyset\right]=\frac{K-1}{K} \\
\mathbf{E}[B]=\frac{K-1}{K} \mathbf{E}\left[\sum_{t=1}^{T} \mathbb{1}\left[S_{t}=\emptyset\right]\right], \\
\mathbf{E}[C]=\frac{1}{K} \mathbf{E}\left[\sum_{t=1}^{T} \mathbb{1}\left[S_{t}=\emptyset\right]\right]
\end{gathered}
$$

Putting all the information together, we get that

$$
\begin{align*}
\mathbf{E}[M] & =\mathbf{E}[A]+\mathbf{E}[B] \\
& =\mathbf{E}[A]+(K-1) \mathbf{E}[C] \\
& \leq(K-1) \mathbf{E}[A+C] \\
& =(K-1) \mathbf{E}[U] \tag{15}
\end{align*}
$$

To finish the proof, we need to upper bound the number of updates $U$. We claim that $U \leq\left\lfloor 4(R / \gamma)^{2}\right\rfloor$ with probability 1. The proof of this upper bound is similar to the proof of the mistake bound for Multiclass PercepTRON algorithm. Let $w_{1}^{*}, w_{2}^{*}, \ldots, w_{K}^{*} \in V$ be vectors that satisfy (3), (4) and (5). The $K$-tuple $\left(w_{1}^{(t)}, w_{2}^{(t)}, \ldots, w_{K}^{(t)}\right)$ changes only if there is an update in round $t$. We investigate how $\sum_{i=1}^{K}\left\|w_{i}^{(t)}\right\|^{2}$ and $\sum_{i=1}^{K}\left\langle w_{i}^{*}, w_{i}^{(t)}\right\rangle$ change. If there is an update in round $t$, by lines 12 and 18 , we always have $w_{\widehat{y}_{t}}^{(t+1)}=w_{\widehat{y}_{t}}^{(t)}+(-1)^{z_{t}} x_{t}$, and for all $i \neq \widehat{y}_{t}$, $w_{i}^{(t+1)}=w_{i}^{(t)}$. Therefore,

$$
\sum_{i=1}^{K}\left\|w_{i}^{(t+1)}\right\|^{2}=\left(\sum_{i \in\{1,2, \ldots, K\} \backslash\left\{\widehat{y}_{t}\right\}}\left\|w_{i}^{(t)}\right\|^{2}\right)+\left\|w_{\widehat{y}_{t}}^{(t+1)}\right\|^{2}
$$

$$
\begin{aligned}
& =\left(\sum_{i \in\{1,2, \ldots, K\} \backslash\left\{\widehat{y}_{t}\right\}}\left\|w_{i}^{(t)}\right\|^{2}\right)+\left\|w_{\widehat{y}_{t}}^{(t)}+(-1)^{z_{t}} x_{t}\right\|^{2} \\
& =\left(\sum_{i=1}^{K}\left\|w_{i}^{(t)}\right\|^{2}\right)+\left\|x_{t}\right\|^{2}+\underbrace{(-1)^{z_{t}} 2\left\langle w_{\widehat{y}_{t}}^{(t)}, x_{t}\right\rangle}_{\leq 0} \\
& \leq\left(\sum_{i=1}^{K}\left\|w_{i}^{(t)}\right\|^{2}\right)+\left\|x_{t}\right\|^{2} \\
& \leq\left(\sum_{i=1}^{K}\left\|w_{i}^{(t)}\right\|^{2}\right)+R^{2} .
\end{aligned}
$$

The inequality that $(-1)^{z_{t}} 2\left\langle w_{\widehat{y}_{t}}^{(t)}, x_{t}\right\rangle \leq 0$ is from a case analysis: if line 12 is executed, then $z_{t}=0$ and $\left\langle w_{\widehat{y}_{t}}^{(t)}, x_{t}\right\rangle<0$; otherwise line 18 is executed, in which case $z_{t}=1$ and $\left\langle w_{\widehat{y}_{t}}^{(t)}, x_{t}\right\rangle \geq 0$.

Hence, after $U$ updates,

$$
\begin{equation*}
\sum_{i=1}^{K}\left\|w_{i}^{(T+1)}\right\|^{2} \leq R^{2} U \tag{16}
\end{equation*}
$$

Similarly, if there is an update in round $t$, we have

$$
\begin{aligned}
\sum_{i=1}^{K}\left\langle w_{i}^{*}, w_{i}^{(t)}\right\rangle & =\left(\sum_{i \in\{1,2, \ldots, K\} \backslash\left\{\widehat{y}_{t}\right\}}\left\langle w_{i}^{*}, w_{i}^{(t)}\right\rangle\right)+\left\langle w_{\widehat{y}_{t}}^{*}, w_{\widehat{y}_{t}}^{(t+1)}\right\rangle \\
& =\left(\sum_{i \in\{1,2, \ldots, K\} \backslash\left\{\widehat{y}_{t}\right\}}\left\langle w_{i}^{*}, w_{i}^{(t)}\right\rangle\right)+\left\langle w_{\widehat{y}_{t}}^{*}, w_{\widehat{y}_{t}}^{(t)}+(-1)^{z_{t}} x_{t}\right\rangle \\
& =\left(\sum_{i=1}^{K}\left\langle w_{i}^{*}, w_{i}^{(t)}\right\rangle\right)+(-1)^{z_{t}}\left\langle w_{\widehat{y}_{t}}^{*}, x_{t}\right\rangle \\
& \geq\left(\sum_{i=1}^{K}\left\langle w_{i}^{*}, w_{i}^{(t)}\right\rangle\right)+\frac{\gamma}{2}
\end{aligned}
$$

where the last inequality follows from a case analysis on $z_{t}$ and Definition 1 : if $z_{t}=0$, then $\widehat{y}_{t}=y_{t}$, by Equation (4), we have that $\left\langle w_{\widehat{y}_{t}}^{*}, x_{t}\right\rangle \geq \frac{\gamma}{2}$; if $z_{t}=1$, then $\widehat{y}_{t} \neq y_{t}$, by Equation (5), we have that $\left\langle w_{\widehat{y}_{t}}^{*}, x_{t}\right\rangle \leq-\frac{\gamma}{2}$.

Thus, after $U$ updates,

$$
\begin{equation*}
\sum_{i=1}^{K}\left\langle w_{i}^{*}, w_{i}^{(T+1)}\right\rangle \geq \frac{\gamma U}{2} \tag{17}
\end{equation*}
$$

Applying Cauchy-Schwartz's inequality twice, and using assumption (3), we get that

$$
\begin{aligned}
\sum_{i=1}^{K}\left\langle w_{i}^{*}, w_{i}^{(T+1)}\right\rangle & \leq \sum_{i=1}^{K}\left\|w_{i}^{*}\right\| \cdot\left\|w_{i}^{(T+1)}\right\| \\
& \leq \sqrt{\sum_{i=1}^{K}\left\|w_{i}^{*}\right\|^{2}} \sqrt{\sum_{i=1}^{K}\left\|w_{i}^{(T+1)}\right\|^{2}} \\
& \leq \sqrt{\sum_{i=1}^{K}\left\|w_{i}^{(T+1)}\right\|^{2}}
\end{aligned}
$$

Combining the above inequality with Equations (16) and (17), we get

$$
\left(\frac{\gamma U}{2}\right)^{2} \leq \sum_{i=1}^{K}\left\|w_{i}^{(T+1)}\right\|^{2} \leq R^{2} U
$$

We conclude that $U \leq 4(R / \gamma)^{2}$. Since $U$ is an integer, $U \leq\left\lfloor 4(R / \gamma)^{2}\right\rfloor$.
Applying Equation (15), we get

$$
\mathbf{E}[M] \leq(K-1) \mathbf{E}[U] \leq(K-1)\left\lfloor 4(R / \gamma)^{2}\right\rfloor
$$

Proof of Theorem 3. Let $M=\left\lfloor\frac{1}{4}(R / \gamma)^{2}\right\rfloor$. Let $V=\mathbb{R}^{M+1}$ equipped with the standard inner product. Let $e_{1}, e_{2}, \ldots, e_{M+1}$ be the standard orthonormal basis of $V$. We define vectors $v_{1}, v_{2}, \ldots, v_{M} \in V$ where $v_{j}=\frac{R}{\sqrt{2}}\left(e_{j}+e_{M+1}\right)$ for $j=1,2, \ldots, M$. Let $\ell_{1}, \ell_{2}, \ldots, \ell_{M}$ be chosen i.i.d. uniformly at random from $\{1,2, \ldots, K\}$ and independently of any randomness used the by algorithm $\mathcal{A}$. Let $T=M(K-1)$. We define examples $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right)$ as follows. For any $j=1,2, \ldots, M$ and any $h=1,2, \ldots, K-1$,

$$
\left(x_{(j-1)(K-1)+h}, y_{(j-1)(K-1)+h}\right)=\left(v_{j}, \ell_{j}\right)
$$

The norm of each example is exactly $R$. The examples are strongly linearly separable with margin $\gamma$. To see that, consider $w_{1}^{*}, w_{2}^{*}, \ldots, w_{K}^{*} \in V$ defined by

$$
w_{i}^{*}=\sqrt{2} \frac{\gamma}{R}\left(\sum_{j: \ell_{j}=i} e_{j}\right)-\frac{\sqrt{2}}{2} \frac{\gamma}{R} e_{M+1}
$$

for $i=1,2, \ldots, K$.
For $i \in\{1,2, \ldots, K\}$ and $j \in\{1,2, \ldots, M\}$, consider the inner product of $w_{i}^{*}$ and $v_{j}$. If $i=\ell_{j},\left\langle w_{i}^{*}, v_{j}\right\rangle=$ $\gamma-\frac{\gamma}{2}=\frac{\gamma}{2}$; otherwise $i \neq \ell_{j}$, in which case $\left\langle w_{i}^{*}, v_{j}\right\rangle=0-\frac{\gamma}{2}=-\frac{\gamma}{2}$. This means that $w_{1}^{*}, w_{2}^{*}, \ldots, w_{K}^{*}$ satisfy conditions (4) and (5). Condition (3) is satisfied since

$$
\sum_{i=1}^{K}\left\|w_{i}^{*}\right\|^{2}=2 \frac{\gamma^{2}}{R^{2}} \sum_{j=1}^{M}\left\|e_{j}\right\|^{2}+\frac{\gamma^{2}}{2 R^{2}} K\left\|e_{M+1}\right\|^{2}=2 \frac{\gamma^{2}}{R^{2}} M+\frac{\gamma^{2}}{2 R^{2}} K \leq \frac{1}{2}+\frac{1}{2}=1
$$

It remains to lower bound the expected number of mistakes of $\mathcal{A}$. For any $j \in\{1,2, \ldots, M\}$, consider the expected number of mistakes the algorithm makes in rounds $(K-1)(j-1)+1,(K-1)(j-1)+2, \ldots,(K-1) j$.

Define a filtration of $\sigma$-algebras $\left\{\mathcal{B}_{j}\right\}_{j=0}^{M}$, where $\mathcal{B}_{j}=\sigma\left(\left(x_{1}, y_{1}, \hat{y}_{1}\right), \ldots,\left(x_{(K-1) j}, y_{(K-1) j}, \hat{y}_{(K-1) j}\right)\right)$ for every $j$ in $\{1,2, \ldots, M\}$. By Claim 2 of Daniely and Helbertal [2013], as $\ell_{j}$ is chosen uniformly from $\{1, \ldots, K\}$ and independent of $\mathcal{B}_{j-1}$ and $\mathcal{A}$ 's randomness,

$$
\mathbf{E}\left[\sum_{t=(K-1)(j-1)+1}^{(K-1) j} z_{t} \mid \mathcal{B}_{j-1}\right] \geq \frac{K-1}{2} .
$$

This implies that

$$
\mathbf{E}\left[\sum_{t=(K-1)(j-1)+1}^{(K-1) j} z_{t}\right] \geq \frac{K-1}{2}
$$

Summing over all $j$ in $\{1,2, \ldots, M\}$,

$$
\mathbf{E}\left[\sum_{t=1}^{(K-1) M} z_{t}\right] \geq \frac{K-1}{2} \cdot M=\frac{K-1}{2}\left\lfloor\frac{1}{4}(R / \gamma)^{2}\right\rfloor .
$$

Thus there exists a particular sequence of examples for which the algorithm makes at least $\frac{K-1}{2}\left\lfloor\frac{1}{4}(R / \gamma)^{2}\right\rfloor$ mistakes in expectation over its internal randomization.

## C Proof of Lemma 9

Proof. Note that the polynomial $p$ can be written as $p(x)=\sum_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}} c_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}^{\prime} x_{1}^{\alpha_{1}} x_{2}^{\alpha_{2}} \ldots x_{d}^{\alpha_{d}}$. We define $c \in \ell_{2}$ using the multi-index notation as

$$
c_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}=\frac{c_{\alpha_{1}, \alpha_{2}, \ldots,,_{d}}^{\prime} 2^{\left(\alpha_{1}+\alpha_{2}+\cdots+\alpha_{d}\right) / 2}}{\sqrt{\binom{\alpha_{1}+\alpha_{2}+\cdots+\alpha_{d}}{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}}}
$$

for all tuples $\left(\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}\right)$ such that $\alpha_{1}+\alpha_{2}+\cdots+\alpha_{d} \leq \operatorname{deg}(p)$. Otherwise, we define $c_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}=0$. By the definition of $\phi,\langle c, \phi(x)\rangle_{\ell_{2}}=p(x)$.

Whether $\alpha_{1}+\ldots+\alpha_{d} \leq \operatorname{deg}(p)$, we always have:

$$
\left|c_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}\right| \leq 2^{\left(\alpha_{1}+\alpha_{2}+\cdots+\alpha_{d}\right) / 2}\left|c_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}^{\prime}\right| \leq 2^{\operatorname{deg}(p) / 2}\left|c_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}^{\prime}\right|
$$

Therefore,

$$
\|c\|_{\ell_{2}} \leq 2^{\operatorname{deg}(p) / 2} \sqrt{\sum_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}\left(c_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}^{\prime}\right)^{2}}=2^{\operatorname{deg}(p) / 2}\|p\|
$$

## D Proof of Theorems 7 and 8

In this section, we follow the construction of Klivans and Servedio [2008] (which in turn uses the constructions of Beigel et al. [1995]) to establish two polynomials of low norm, such that it takes large positive values in

$$
\bigcap_{i=1}^{m}\left\{x \in \mathbb{R}^{d}:\|x\| \leq 1,\left\langle v_{i}, x\right\rangle \geq \gamma\right\}
$$

and takes large negative values in

$$
\bigcup_{i=1}^{m}\left\{x \in \mathbb{R}^{d}:\|x\| \leq 1,\left\langle v_{i}, x\right\rangle \leq-\gamma\right\}
$$

We improve the norm bound analysis of Klivans and Servedio [2008] in two aspects:

1. Our upper bounds on the norm of the polynomials do not have any dependency on the dimensionality $d$.
2. We remove the requirement that the fractional part of input $x$ must be above some threshold in Theorem 8 .

A lot of the proof details are similar to those of Klivans and Servedio [2008]; nevertheless, we provide a self-contained full proof here.

For the proofs of the theorems we need several auxiliary results.
Lemma 12 (Simple inequality). For any real numbers $b_{1}, b_{2}, \ldots, b_{n}$,

$$
\left(\sum_{i=1}^{n} b_{i}\right)^{2} \leq n \sum_{i=1}^{n} b_{i}^{2}
$$

Proof. The lemma follows from Cauchy-Schwartz inequality applied to vectors $\left(b_{1}, b_{2}, \ldots, b_{n}\right)$ and $(1,1, \ldots, 1)$.
Lemma 13 (Bound on binomial coefficients). For any integers $n, k$ such that $n \geq k \geq 0$,

$$
\binom{n}{k} \leq(n-k+1)^{k}
$$

Proof. If $k=0$, the inequality trivially holds. For the rest of the proof we can assume $k \geq 1$. We write the binomial coefficient as

$$
\begin{aligned}
\binom{n}{k} & =\frac{n(n-1) \cdots(n-k+1)}{k(k-1) \cdots 1} \\
& =\frac{n}{k} \cdot \frac{n-1}{k-1} \cdots \frac{n-k+1}{1} .
\end{aligned}
$$

We claim that

$$
\frac{n}{k} \leq \frac{n-1}{k-1} \leq \cdots \leq \frac{n-k+1}{1}
$$

from which the lemma follows by upper bounding all the fractions by $n-k+1$. It remains to prove that for any $j=0,1, \ldots, k-1$,

$$
\frac{n-j+1}{k-j+1} \leq \frac{n-j}{k-j}
$$

Multiplying by the (positive) denominators, we get an equivalent inequality

$$
(n-j+1)(k-j) \leq(n-j)(k-j+1) .
$$

Cancelling common terms leads to an equivalent inequality

$$
k-j \leq n-j,
$$

which since $n \geq k$ by assumption.
Lemma 14 (Properties of the norm of polynomials).

1. Let $p_{1}, p_{2}, \ldots, p_{n}$ be multivariate polynomials and let $p(x)=\prod_{j=1}^{n} p_{j}(x)$ be their product. Then, $\|p\|^{2} \leq$ $n^{\sum_{j=1}^{n} \operatorname{deg}\left(p_{j}\right)} \prod_{j=1}^{n}\left\|p_{j}\right\|^{2}$.
2. Let $q$ be a multivariate polynomial of degree at most $s$ and let $p(x)=(q(x))^{n}$. Then, $\|p\|^{2} \leq n^{n s}\|q\|^{2 n}$.
3. Let be $p_{1}, p_{2}, \ldots, p_{n}$ be multivariate polynomials. Then, $\left\|\sum_{j=1}^{n} p_{j}\right\|^{2} \leq n \sum_{j=1}^{n}\left\|p_{j}\right\|^{2}$.

Proof. Using multi-index notation we can write any multivariate polynomial $p$ as

$$
p(x)=\sum_{A} c_{A} x^{A}
$$

where $A=\left(\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}\right)$ is a multi-index (i.e. a $d$-tuple of non-negative integers), $x^{A}=x_{1}^{\alpha_{1}} x_{2}^{\alpha_{2}} \ldots x_{d}^{\alpha_{d}}$ is a monomial and $c_{A}=c_{\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}}$ is the corresponding real coefficient. The sum is over a finite subset of $d$-tuples of non-negative integers. Using this notation, the norm of a polynomial $p$ can be written as

$$
\|p\|=\sqrt{\sum_{A}\left(c_{A}\right)^{2}}
$$

For a multi-index $A=\left(\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}\right)$ we define its 1-norm as $\|A\|_{1}=\alpha_{1}+\alpha_{2}+\cdots+\alpha_{d}$.
To prove the part 1 , we express $p_{j}$ as

$$
p_{j}(x)=\sum_{A_{j}} c_{A_{j}}^{(j)} x^{A_{j}}
$$

Since $p(x)=\prod_{i=1}^{n} p_{j}(x)$, the coefficients of its expansion $p(x)=\sum_{A} c_{A} x^{A}$ are

$$
c_{A}=\sum_{\substack{\left(A_{1}, A_{2}, \ldots, A_{n}\right) \\ A_{1}+A_{2}+\cdots+A_{n}=A}} c_{A_{1}}^{(1)} c_{A_{2}}^{(2)} \cdots c_{A_{n}}^{(n)}
$$

Therefore,

$$
\begin{aligned}
\|p\|^{2} & =\sum_{A}\left(c_{A}\right)^{2} \\
& =\sum_{A}\left(\sum_{\substack{\left(A_{1}, A_{2}, \ldots, A_{n}\right) \\
A_{1}+A_{2}+\cdots+A_{n}=A}} c_{A_{1}}^{(1)} c_{A_{2}}^{(2)} \cdots c_{A_{n}}^{(n)}\right)^{2} \\
& =\sum_{A}\left(\sum_{\substack{\left(A_{1}, A_{2}, \ldots, A_{n}\right) \\
A_{1}+A_{2}+\cdots+A_{n}=A}} \prod_{j=1}^{n} c_{A_{j}}^{(j)}\right)^{2}
\end{aligned}
$$

and

$$
\begin{aligned}
\prod_{i=1}^{n}\left\|p_{i}\right\|^{2} & =\prod_{i=1}^{n}\left(\sum_{A_{i}}\left(c_{A_{i}}^{(i)}\right)^{2}\right) \\
& =\sum_{\left(A_{1}, A_{2}, \ldots, A_{n}\right)} \prod_{j=1}^{n}\left(c_{A_{j}}^{(j)}\right)^{2} \\
& =\sum_{\left(A_{1}, A_{2}, \ldots, A_{n}\right)}\left(\prod_{j=1}^{n} c_{A_{j}}^{(j)}\right)^{2} \\
& =\sum_{A} \sum_{\substack{\left(A_{1}, A_{2}, \ldots, A_{n}\right) \\
A_{1}+A_{2}+\cdots+A_{n}=A}}\left(\prod_{j=1}^{n} c_{A_{j}}^{(j)}\right)^{2}
\end{aligned}
$$

where in both cases the outer sum is over multi-indices $A$ such that $\|A\|_{1} \leq \operatorname{deg}(p)$. Lemma 12 implies that for any multi-index $A$,

$$
\left(\sum_{\substack{\left(A_{1}, A_{2}, \ldots, A_{n}\right) \\ A_{1}+A_{2}+\cdots+A_{n}=A}} \prod_{j=1}^{n} c_{A_{j}}^{(j)}\right)^{2} \leq M_{A} \sum_{\substack{\left(A_{1}, A_{2}, \ldots, A_{n}\right) \\ A_{1}+A_{2}+\cdots+A_{n}=A}}\left(\prod_{j=1}^{n} c_{A_{j}}^{(j)}\right)^{2}
$$

where $M_{A}$ is the number of $n$-tuples $\left(A_{1}, A_{2}, \ldots, A_{n}\right)$ such that $A_{1}+A_{2}+\cdots+A_{n}=A$.
To finish the proof, it is sufficient to prove that $M_{A} \leq n^{\operatorname{deg}(p)}$ for any $A$ such that $\|A\|_{1} \leq \operatorname{deg}(p)$. To prove this inequality, consider a multi-index $A=\left(\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}\right)$ and consider its $i$-th coordinate $\alpha_{i}$. In order for $A_{1}+$ $A_{2}+\cdots+A_{n}=A$ to hold, the $i$-th coordinates of $A_{1}, A_{2}, \ldots, A_{n}$ need to sum to $\alpha_{i}$. There are exactly $\binom{\alpha_{i}+n-1}{\alpha_{i}}$ possibilities for the choice of $i$-th coordinates of $A_{1}, A_{2}, \ldots, A_{n}$. The total number of choices is thus

$$
M_{A}=\prod_{i=1}^{d}\binom{\alpha_{i}+n-1}{\alpha_{i}}
$$

Using Lemma 13, we upper bound it as

$$
M_{A} \leq \prod_{i=1}^{d} n^{\alpha_{i}}=n^{\|A\|_{1}} \leq n^{\operatorname{deg}(p)}
$$

Part 2 follows from the part 1 by setting $p_{1}=p_{2}=\ldots p_{n}=q$.
To prove part 3, we use generalized triangle inequality and Lemma 12. We have

$$
\left\|\sum_{j=1}^{n} p_{j}\right\|^{2}=\left(\left\|\sum_{j=1}^{n} p_{j}\right\|\right)^{2} \leq\left(\sum_{j=1}^{n}\left\|p_{j}\right\|\right)^{2} \leq n \sum_{j=1}^{n}\left\|p_{j}\right\|^{2} .
$$

## D. 1 Proof of Theorem 7

To construct the polynomial $p$ we use Chebyshev polynomials of the first kind. Chebyshev polynomials of the fist kind form an infinite sequence of polynomials $T_{0}(z), T_{1}(z), T_{2}(z), \ldots$ of single real variable $z$. They are defined by the recurrence

$$
\begin{aligned}
T_{0}(z) & =1 \\
T_{1}(z) & =z \\
T_{n+1}(z) & =2 z T_{n}(z)-T_{n-1}(z), \quad \text { for } n \geq 1
\end{aligned}
$$

Chebyshev polynomials have a lot of interesting properties. We will need properties listed in Proposition 15 below. Interested reader can learn more about Chebyshev polynomials from the book by Mason and Handscomb [2002].

Proposition 15 (Properties of Chebyshev polynomials). Chebyshev polynomials satisfy

1. $\operatorname{deg}\left(T_{n}\right)=n$ for all $n \geq 0$.
2. If $n \geq 1$, the leading coefficient of $T_{n}(z)$ is $2^{n-1}$.
3. $T_{n}(\cos (\theta))=\cos (n \theta)$ for all $\theta \in \mathbb{R}$ and all $n \geq 0$.
4. $T_{n}(\cosh (\theta))=\cosh (n \theta)$ for all $\theta \in \mathbb{R}$ and all $n \geq 0$.
5. $\left|T_{n}(z)\right| \leq 1$ for all $z \in[-1,1]$ and all $n \geq 0$.
6. $T_{n}(z) \geq 1+n^{2}(z-1)$ for all $z \geq 1$ and all $n \geq 0$.
7. $\left\|T_{n}\right\| \leq(1+\sqrt{2})^{n}$ for all $n \geq 0$

Proof of Proposition 15. The first two properties can be easily proven by induction on $n$ using the recurrence.
We prove the third property by induction on $n$. Indeed, by definition

$$
T_{0}(\cos (\theta))=1=\cos (0 \theta) \quad \text { and } \quad T_{1}(\cos (\theta))=\cos (\theta)
$$

For $n \geq 1$, we have

$$
\begin{aligned}
T_{n+1}(\cos (\theta)) & =2 \cos (\theta) T_{n}(\cos (\theta))-T_{n-1}(\cos (\theta)) \\
& =2 \cos (\theta) \cos (n \theta)-\cos ((n-1) \theta)),
\end{aligned}
$$

where the last step follow by induction hypothesis. It remains to show that the last expression equals $\cos ((n+1) \theta)$. This can be derived from the trigonometric formula

$$
\cos (\alpha \pm \beta)=\cos (\alpha) \cos (\beta) \mp \sin (\alpha) \sin (\beta)
$$

By substituting $\alpha=n \theta$ and $\beta=\theta$, we get two equations

$$
\begin{aligned}
& \cos ((n+1) \theta)=\cos (n \theta) \cos (\theta)-\sin (n \theta) \sin (\theta) \\
& \cos ((n-1) \theta)=\cos (n \theta) \cos (\theta)+\sin (n \theta) \sin (\theta)
\end{aligned}
$$

Summing them yields

$$
\cos ((n+1) \theta)+\cos ((n-1) \theta)=2 \cos (n \theta) \cos (\theta)
$$

which finishes the proof.
The fourth property has the similar proof as the third property. It suffices to replace $\cos$ and $\sin$ with cosh and sinh respectively.

The fifth property follows from the third property. Indeed, for any $z \in[-1,1]$ there exists $\theta \in \mathbb{R}$ such that $\cos \theta=z$. Thus, $\left|T_{n}(z)\right|=\left|T_{n}(\cos (\theta))\right|=|\cos (n \theta)| \leq 1$.

The sixth property is equivalent to

$$
T_{n}(\cosh (\theta)) \geq 1+n^{2}(\cosh (\theta)-1) \quad \text { for all } \theta \geq 0
$$

since $\cosh (\theta)=\frac{e^{\theta}+e^{-\theta}}{2}$ is an even continuous function that maps $\mathbb{R}$ onto $[1,+\infty)$, is strictly decreasing on $(-\infty, 0]$, and is strictly increasing on $[0, \infty)$. Using the fourth property the last inequality is equivalent to

$$
\cosh (n \theta) \geq 1+n^{2}(\cosh (\theta)-1) \quad \text { for all } \theta \geq 0
$$

For $\theta=0$, both sides are equal to 1 . Thus, it is sufficient to prove that the derivative of the left hand side is greater or equal to the derivative of the right hand side. Recalling that $[\cosh (\theta)]^{\prime}=\sinh (\theta)$, this means that we need to show that

$$
\sinh (n \theta) \geq n \sinh (\theta) \quad \text { for all } \theta \geq 0
$$

Tho prove this inequality we use the summation formula

$$
\sinh (\alpha+\beta)=\sinh (\alpha) \cosh (\beta)+\sinh (\beta) \cosh (\beta)
$$

If $\alpha, \beta$ are non-negative then $\sinh (\alpha), \sinh (\beta)$ are non-negative and $\cosh (\alpha), \cosh (\beta) \geq 1$. Hence,

$$
\sinh (\alpha+\beta) \geq \sinh (\alpha)+\sinh (\beta) \quad \text { for any } \alpha, \beta \geq 0
$$

This implies that (using induction on $n$ ) that $\sinh (n \theta) \geq n \sinh (\theta)$ for all $\theta \geq 0$.

We verify the seventh property by induction on $n$. For $n=0$ and $n=1$ the inequality trivially holds, since $\left\|T_{0}\right\|=\left\|T_{1}\right\|=1$. For $n \geq 1$, since $T_{n+1}(z)=2 z T_{n}(z)-T_{n-1}(z)$,

$$
\begin{aligned}
\left\|T_{n+1}\right\| & \leq 2\left\|T_{n}\right\|+\left\|T_{n-1}\right\| \\
& \leq 2(1+\sqrt{2})^{n}+(1+\sqrt{2})^{n-1} \\
& =(1+\sqrt{2})^{n-1}(2(1+\sqrt{2})+1) \\
& =(1+\sqrt{2})^{n-1}(3+2 \sqrt{2}) \\
& =(1+\sqrt{2})^{n-1}(1+\sqrt{2})^{2} \\
& =(1+\sqrt{2})^{n+1}
\end{aligned}
$$

We are now ready to prove Theorem 7. Let $r=\left\lceil\log _{2}(2 m)\right\rceil$ and $s=\left\lceil\sqrt{\frac{1}{\gamma}}\right\rceil$. We define the polynomial $p: \mathbb{R}^{d} \rightarrow \mathbb{R}$ as

$$
p(x)=m+\frac{1}{2}-\sum_{i=1}^{m}\left(T_{s}\left(1-\left\langle v_{i}, x\right\rangle\right)\right)^{r}
$$

It remains to show that $p$ has properties 1-5.
To verify the first property notice that if $x \in \mathbb{R}^{d}$ satisfies $\|x\| \leq 1$ and $\left\langle v_{i}, x\right\rangle \geq \gamma$ then since $\left\|v_{i}\right\| \leq 1$ we have $\left\langle v_{i}, x\right\rangle \in[0,1]$. Thus, $T_{s}\left(1-\left\langle v_{i}, x\right\rangle\right)$ and $\left(T_{s}\left(1-\left\langle v_{i}, x\right\rangle\right)\right)^{r}$ lie in the interval $[-1,1]$. Therefore,

$$
p(x) \geq m+\frac{1}{2}-m \geq \frac{1}{2}
$$

To verify the second property consider any $x \in \bigcup_{i=1}^{m}\left\{x \in \mathbb{R}^{d}:\|x\| \leq 1,\left\langle v_{i}, x\right\rangle \leq-\gamma\right\}$. Clearly, $\|x\| \leq 1$ and there exists at least one $i \in\{1,2, \ldots, m\}$ such that $\left\langle v_{i}, x\right\rangle \leq-\gamma$. Therefore, $1-\left\langle v_{i}, x\right\rangle \geq 1+\gamma$ and Proposition 15 (part 6) imply that

$$
T_{s}\left(1-\left\langle v_{i}, x\right\rangle\right) \geq 1+s^{2} \gamma \geq 2
$$

and thus

$$
\left(T_{s}\left(1-\left\langle v_{i}, x\right\rangle\right)\right)^{r} \geq 2^{r} \geq 2 m
$$

On the other hand for any $j \in\{1,2, \ldots, m\}$, we have $\left\langle v_{j}, x\right\rangle \in[-1,1]$ and thus $1-\left\langle v_{j}, x\right\rangle$ lies in the interval [0, 2]. According to Proposition 15 (parts 5 and 6), $T_{s}\left(1-\left\langle v_{j}, x\right\rangle\right) \geq-1$. Therefore,

$$
\begin{aligned}
p(x) & =m+\frac{1}{2}-\left(T_{s}\left(1-\left\langle v_{i}, x\right\rangle\right)\right)^{r}-\sum_{\substack{j: 1 \leq j \leq m \\
j \neq i}}\left(T_{s}\left(1-\left\langle v_{j}, x\right\rangle\right)\right)^{r} \\
& \leq m+\frac{1}{2}-2 m+(m-1) \leq-\frac{1}{2}
\end{aligned}
$$

The third property follows from the observation that the degree of $p$ is the same as the degree of any one of the terms $\left(T_{s}\left(1-\left\langle v_{i}, x\right\rangle\right)\right)^{r}$ which is $r \cdot s$.

To prove the fourth property, we need to upper bound the norm of $p$. Let $f_{i}(x)=1-\left\langle v_{i}, x\right\rangle$, let $g_{i}(x)=$ $T_{s}\left(1-\left\langle v_{i}, x\right\rangle\right)$ and let $h_{i}(x)=\left(T_{s}\left(1-\left\langle v_{i}, x\right\rangle\right)\right)^{r}$. We have

$$
\left\|f_{i}\right\|^{2}=1+\left\|v_{i}\right\|^{2} \leq 1+1=2
$$

Let $T_{s}(z)=\sum_{j=0}^{s} c_{j} z^{j}$ be the expansion of $s$-th Chebyshev polynomial. Then,

$$
\left\|g_{i}\right\|^{2}=\left\|\sum_{j=0}^{s} c_{j}\left(f_{i}\right)^{j}\right\|^{2}
$$

$$
\begin{aligned}
& \leq(s+1) \sum_{j=0}^{s}\left\|c_{j}\left(f_{i}\right)^{j}\right\|^{2} \quad \text { by part } 3 \text { of Lemma 14) } \\
& =(s+1) \sum_{j=0}^{s}\left(c_{j}\right)^{2}\left\|\left(f_{i}\right)^{j}\right\|^{2} \\
& \leq(s+1) \sum_{j=0}^{s}\left(c_{j}\right)^{2} j^{j}\left\|f_{i}\right\|^{2 j} \quad \text { (by part } 2 \text { of Lemma 14) } \\
& \leq(s+1) \sum_{j=0}^{s}\left(c_{j}\right)^{2} j^{j} 2^{2 j} \\
& \leq(s+1) s^{s} 2^{2 s} \sum_{j=0}^{s}\left(c_{j}\right)^{2} \\
& =(s+1) s^{s} 2^{2 s}\left\|T_{s}\right\|^{2} \\
& =(s+1) s^{s} 2^{2 s}(1+\sqrt{2})^{2 s} \quad \text { (by part } 7 \text { of Proposition 15) } \\
& =(s+1)\left(4(1+\sqrt{2})^{2} s\right)^{s} \\
& \leq\left(8(1+\sqrt{2})^{2} s\right)^{s} \\
& \leq(47 s)^{s}
\end{aligned}
$$

where we used that $s+1 \leq 2^{s}$ for any non-negative integer $s$. Finally,

$$
\begin{aligned}
\|p\| & \leq m+\frac{1}{2}+\sum_{i=1}^{m}\left\|\left(g_{i}\right)^{r}\right\| \\
& =m+\frac{1}{2}+\sum_{i=1}^{m} \sqrt{\left\|\left(g_{i}\right)^{r}\right\|^{2}} \\
& \leq m+\frac{1}{2}+\sum_{i=1}^{m} \sqrt{r^{r s}\left\|g_{i}\right\|^{2 r}} \\
& \leq m+\frac{1}{2}+m r^{r s / 2}(47 s)^{r s / 2} \\
& =m+\frac{1}{2}+m(47 r s)^{r s / 2}
\end{aligned}
$$

We can further upper bound the last expression by using that $m \leq \frac{1}{2} 2^{r}$. Since $r, s \geq 1$,

$$
\begin{aligned}
\|p\| & \leq m+\frac{1}{2}+m(47 r s)^{r s / 2} \\
& \leq \frac{1}{2} 2^{r}+\frac{1}{2}+\frac{1}{2} 2^{r}(47 r s)^{r s / 2} \\
& \leq 2^{r}+\frac{1}{2} 2^{r}(47 r s)^{r s / 2} \\
& =2^{r}\left(1+\frac{1}{2}(47 r s)^{r s / 2}\right) \\
& =2^{r}(47 r s)^{r s / 2} \\
& \leq 4^{r s / 2}(47 r s)^{r s / 2} \\
& \leq(188 r s)^{r s / 2}
\end{aligned}
$$

Substituting for $r$ and $s$ finishes the proof.

## D. 2 Proof of Theorem 8

We prove the following lemma in this section. Theorem 8 immediately follows from this lemma by considering $p^{\prime}=p \cdot 2^{-s(s+1) r m+1}$ and algebra.
Lemma 16. Let $v_{1}, v_{2}, \ldots, v_{m} \in \mathbb{R}^{d}$ be vectors such that $\left\|v_{1}\right\|,\left\|v_{2}\right\|, \ldots,\left\|v_{m}\right\| \leq 1$. Let $\gamma \in(0,1)$. Define

$$
r=2\left\lceil\frac{1}{4} \log _{2}(4 m+1)\right\rceil+1 \quad \text { and } \quad s=\left\lceil\log _{2}(1 / \gamma)\right\rceil
$$

Then, there exists a multivariate polynomial $p: \mathbb{R}^{d} \rightarrow \mathbb{R}$ such that

1. $p(x) \geq \frac{1}{4} \cdot 2^{s(s+1) r m}$ for all $x \in \bigcap_{i=1}^{m}\left\{x \in \mathbb{R}^{d}:\|x\| \leq 1,\left\langle v_{i}, x\right\rangle \geq \gamma\right\}$,
2. $p(x) \leq-\frac{1}{4} \cdot 2^{s(s+1) r m}$ for all $x \in \bigcup_{i=1}^{m}\left\{x \in \mathbb{R}^{d}:\|x\| \leq 1,\left\langle v_{i}, x\right\rangle \leq-\gamma\right\}$,
3. $\operatorname{deg}(p) \leq(2 s+1) r m$,
4. $\|p\| \leq(2 m-1 / 2) 2^{m} \cdot\left(2^{2 s} r m(4 s+2)^{2}\right)^{(s+1 / 2) r m}$.

We define several univariate polynomials

$$
\begin{aligned}
P_{n}(z) & =(z-1) \prod_{i=1}^{n}\left(z-2^{i}\right)^{2}, \quad \text { for } n \geq 0 \\
A_{n, k}(z) & =\left(P_{n}(z)\right)^{k}-\left(P_{n}(-z)\right)^{k}, \quad \text { for } n, k \geq 0 \\
B_{n, k}(z) & =-\left(P_{n}(z)\right)^{k}-\left(P_{n}(-z)\right)^{k}, \quad \text { for } n, k \geq 0
\end{aligned}
$$

We define the polynomial $p: \mathbb{R}^{d} \rightarrow \mathbb{R}$ as

$$
p(x)=\left[\sum_{i=1}^{m} A_{s, r}\left(\frac{\left\langle v_{i}, x\right\rangle}{\gamma}\right) \prod_{\substack{1 \leq j \leq m \\ j \neq i}} B_{s, r}\left(\frac{\left\langle v_{j}, x\right\rangle}{\gamma}\right)\right]-\left(m-\frac{1}{2}\right) \prod_{j=1}^{m} B_{s, r}\left(\frac{\left\langle v_{j}, x\right\rangle}{\gamma}\right)
$$

For convenience we define univariate rational function

$$
S_{n, k}(z)=\frac{A_{n, k}(z)}{B_{n, k}(z)}, \quad \text { for } n, k \geq 0
$$

and a multivariate rational function

$$
Q(x)=\left(\sum_{i=1}^{m} S_{s, r}\left(\frac{\left\langle v_{i}, x\right\rangle}{\gamma}\right)\right)-\left(m-\frac{1}{2}\right)
$$

It is easy to verify that

$$
p(x)=Q(x) \prod_{j=1}^{m} B_{s, r}\left(\frac{\left\langle v_{j}, x\right\rangle}{\gamma}\right)
$$

Lemma 17 (Properties of $P_{n}$ ).

1. If $z \in[0,1]$ then $P_{n}(-z) \leq P_{n}(z) \leq 0$.
2. If $z \in\left[1,2^{n}\right]$ then $0 \leq 4 P_{n}(z) \leq-P_{n}(-z)$.
3. If $z \geq 0$ then $-P_{n}(-z) \geq 2^{n(n+1)}$.

Proof. To prove the first part, note that $P_{n}(z)$ and $P_{n}(-z)$ are non-positive for $z \in[0,1]$. We can write $\frac{P_{n}(z)}{P_{n}(-z)}$ as a product of $n+1$ non-negative fractions

$$
\frac{P_{n}(z)}{P_{n}(-z)}=\frac{1-z}{1+z} \prod_{i=1}^{n} \frac{\left(z+2^{i}\right)^{2}}{\left(z-2^{i}\right)^{2}}
$$

The first part follows from the observation that each fraction is upper bounded by 1.
To prove the second part, notice that $P_{n}(z)$ is non-negative and $P_{n}(-z)$ is non-positive for any $z \in\left[1,2^{n}\right]$. Now, fix $z \in\left[1,2^{n}\right]$ and let $j \in\{1,2, \ldots, n\}$ be such that $2^{j-1} \leq z \leq 2^{j}$. This implies that $\left(z+2^{j}\right)^{2} \geq\left(2^{j}\right)^{2} \geq 4\left(z-2^{j}\right)^{2}$. We can write $\frac{P_{n}(z)}{-P_{n}(-z)}$ as a product of $n+1$ non-negative fractions

$$
\frac{P_{n}(z)}{-P_{n}(-z)}=\frac{z-1}{z+1} \cdot \frac{\left(z-2^{j}\right)^{2}}{\left(z+2^{j}\right)^{2}} \prod_{\substack{i \leq i \leq n \\ i \neq j}} \frac{\left(z-2^{i}\right)^{2}}{\left(z+2^{i}\right)^{2}}
$$

The second part follows from the observation that the second fraction is upper bounded by $1 / 4$ and all other fractions are upper bounded by 1 .

The third part follows from

$$
-P_{n}(-z)=(1+z) \prod_{i=1}^{n}\left(z+2^{i}\right)^{2} \geq \prod_{i=1}^{n} 2^{2 i}=2^{n(n+1)}
$$

Lemma 18 (Properties of $S_{n, r}$ and $B_{n, r}$ ). Let $n$, $m$ be non-negative integers. Let $r=2\left\lceil\frac{1}{4} \log _{2}(4 m+1)\right\rceil+1$. Then,

1. If $z \in\left[1,2^{n}\right]$ then $S_{n, r}(z) \in\left[1,1+\frac{1}{2 m}\right]$.
2. If $z \in\left[-2^{n},-1\right]$ then $S_{n, r}(z) \in\left[-1-\frac{1}{2 m},-1\right]$.
3. If $z \in[-1,1]$ then $\left|S_{n, r}(z)\right| \leq 1$.
4. If $z \in\left[-2^{n}, 2^{n}\right]$ then
$B_{n, r}(z) \geq\left(1-\frac{1}{4 m+1}\right) 2^{n(n+1) r}$.
Proof. Note that $B_{n, r}(z)$ is an even function and $A_{n, r}(z)$ is an odd function. Therefore, $S_{n, r}(z)$ is odd. Also notice that $r$ is an odd integer.
5. Observe that $S_{n, r}(z)$ can be written as

$$
S_{n, r}(z)=\frac{1+\left(-\frac{P_{n}(z)}{P_{n}(-z)}\right)^{r}}{1-\left(-\frac{P_{n}(z)}{P_{n}(-z)}\right)^{r}}=\frac{1+c}{1-c}
$$

where $c=\left(-\frac{P_{n}(z)}{P_{n}(-z)}\right)^{r}$. Since $z \in\left[1,2^{n}\right]$, by part 2 of Lemma $17, c \in\left[0, \frac{1}{4^{r}}\right]$. Since $r \geq \frac{1}{2} \log _{2}(4 m+1)$, this means that $c \in\left[0, \frac{1}{4 m+1}\right]$. Thus, $S_{n, r}(z)=\frac{1+c}{1-c} \in\left[1,1+\frac{1}{2 m}\right]$.
2. Since $S_{n, r}(z)$ is odd, the statement follows from part 1.
3. Recall that $S_{n, r}(z)$ can be written as

$$
S_{n, r}(z)=\frac{1+c}{1-c}
$$

where $c=\left(-\frac{P_{n}(z)}{P_{n}(-z)}\right)^{r}$. If $z \in[0,1]$, by part 1 of Lemma 17 and the fact that $r$ is odd, $c \in[-1,0]$, and thus, $S_{n, r}(z)=\frac{1+c}{1-c} \in[0,1]$. Since $S_{n, r}(z)$ is odd, for $z \in[-1,0], S_{n, r}(z) \in[-1,0]$.
4. Since $B_{n, r}(z)$ is even, we can without loss generality assume that $z \geq 0$. We consider two cases.

Case $z \in[0,1]$. Since $r$ is odd and $P_{n}(z)$ is non-positive,

$$
\begin{aligned}
B_{n, r}(z) & =-\left(P_{n}(z)\right)^{r}+\left(-P_{n}(-z)\right)^{r} \\
& \geq\left(-P_{n}(-z)\right)^{r} \geq 2^{n(n+1) r} \\
& \geq 2^{n(n+1) r}\left(1-\frac{1}{4 m+1}\right) .
\end{aligned}
$$

where the second last inequality follows from part 3 of Lemma 17.
Case $z \in\left[1,2^{n}\right]$. Since $r$ is odd,

$$
\begin{aligned}
B_{n, r}(z) & =\left(-P_{n}(-z)\right)^{r}\left(1-\left(-\frac{P_{n}(z)}{P_{n}(-z)}\right)^{r}\right) \\
& =\left(-P_{n}(-z)\right)^{r}(1-c)
\end{aligned}
$$

where $c=\left(-\frac{P_{n}(z)}{P_{n}(-z)}\right)^{r}$. Since $z \in\left[1,2^{n}\right]$, by part 2 of Lemma 17, $c \in\left[0, \frac{1}{4^{r}}\right]$. By the definition of $r$ that means that $c \in\left[0, \frac{1}{4 m+1}\right]$. Thus,

$$
\begin{aligned}
B_{n, r}(z) & \geq\left(-P_{n}(-z)\right)^{r}\left(1-\frac{1}{4 m+1}\right) \\
& \geq 2^{n(n+1) r}\left(1-\frac{1}{4 m+1}\right)
\end{aligned}
$$

where the last inequality follows from part 3 of Lemma 17.

Lemma 19 (Properties of $Q(x)$ ). The rational function $Q(x)$ satisfies

1. $Q(x) \geq \frac{1}{2}$ for all $x \in \bigcap_{i=1}^{m}\left\{x \in \mathbb{R}^{d}:\|x\| \leq 1,\left\langle v_{i}, x\right\rangle \geq \gamma\right\}$,
2. $Q(x) \leq-\frac{1}{2}$ for all $x \in \bigcup_{i=1}^{m}\left\{x \in \mathbb{R}^{d}:\|x\| \leq 1,\left\langle v_{i}, x\right\rangle \leq-\gamma\right\}$.

Proof. To prove part 1, consider any $x \in \bigcap_{i=1}^{m}\left\{x \in \mathbb{R}^{d}:\|x\| \leq 1,\left\langle v_{i}, x\right\rangle \geq \gamma\right\}$. Then, $\frac{\left\langle v_{i}, x\right\rangle}{\gamma} \in\left[1, \frac{1}{\gamma}\right]$. By part 1 of Lemma 18, $S_{s, r}\left(\frac{\left\langle v_{i}, x\right\rangle}{\gamma}\right) \in\left[1,1+\frac{1}{2 m}\right]$ and in particular $S_{s, r}\left(\frac{\left\langle v_{i}, x\right\rangle}{\gamma}\right) \geq 1$. Thus,

$$
\begin{aligned}
Q(x) & =\left(\sum_{i=1}^{m} S_{s, r}\left(\frac{\left\langle v_{i}, x\right\rangle}{\gamma}\right)\right)-(m-1 / 2) \\
& \geq m-(m-1 / 2) \\
& =1 / 2
\end{aligned}
$$

To prove part 2 , consider any $x \in \bigcup_{i=1}^{m}\left\{x \in \mathbb{R}^{d}:\|x\| \leq 1,\left\langle v_{i}, x\right\rangle \leq-\gamma\right\}$. Observe that $\frac{\left\langle v_{i}, x\right\rangle}{\gamma} \in\left[-\frac{1}{\gamma}, \frac{1}{\gamma}\right]$. Consider $S_{s, r}\left(\frac{\left\langle v_{i}, x\right\rangle}{\gamma}\right)$ for any $i \in\{1,2, \ldots, m\}$. Parts 1,2 , and 3 of Lemma 18 and the fact $1 / \gamma \leq 2^{s}$ imply that $S_{s, r}\left(\frac{\left\langle v_{i}, x\right\rangle}{\gamma}\right) \leq 1+\frac{1}{2 m}$ for all $i \in\{1,2, \ldots, m\}$. By the choice of $x$, there exists $j \in\{1,2, \ldots, m\}$ such that $\left\langle v_{j}, x\right\rangle \leq-\gamma$. Part 2 of Lemma 18 implies that $S_{s, r}\left(\frac{\left\langle v_{j}, x\right\rangle}{\gamma}\right) \in\left[-1-\frac{1}{2 m},-1\right]$. Thus,

$$
\begin{aligned}
Q(x) & =\left(\sum_{i=1}^{m} S_{s, r}\left(\frac{\left\langle v_{i}, x\right\rangle}{\gamma}\right)\right)-\left(m-\frac{1}{2}\right) \\
& =S_{s, r}\left(\frac{\left\langle v_{j}, x\right\rangle}{\gamma}\right)+\left(\sum_{\substack{1 \leq i \leq m \\
i \neq j}} S_{s, r}\left(\frac{\left\langle v_{i}, x\right\rangle}{\gamma}\right)\right)-\left(m-\frac{1}{2}\right) \\
& \leq-1+(m-1)\left(1+\frac{1}{2 m}\right)-\left(m-\frac{1}{2}\right) \\
& \leq-1 / 2
\end{aligned}
$$

To prove parts 1 and 2 of Lemma 16 first note that part 4 of Lemma 18 implies that for any $x$ such that $\|x\| \leq$ $1, B_{s, r}\left(\frac{\left\langle v_{i}, x\right\rangle}{\gamma}\right)$ is positive. Thus $p(x)$ and $Q(x)$ have the same sign on the unit ball. Consider any $x$ in either $\bigcap_{i=1}^{m}\left\{x \in \mathbb{R}^{d}:\|x\| \leq 1,\left\langle v_{i}, x\right\rangle \geq \gamma\right\}$ or in $\bigcup_{i=1}^{m}\left\{x \in \mathbb{R}^{d}:\|x\| \leq 1,\left\langle v_{i}, x\right\rangle \leq-\gamma\right\}$. Lemma 19 states that $|Q(x)| \geq$ $1 / 2$ and the sign depends on which of the two sets $x$ lies in. Since signs of $Q(x)$ and $p(x)$ are the same, it remains to show that $|p(x)| \geq \frac{1}{4} \cdot 2^{s(s+1) r m}$. Indeed,

$$
\begin{aligned}
|p(x)| & =|Q(x)| \prod_{j=1}^{m} B_{s, r}\left(\frac{\left\langle v_{j}, x\right\rangle}{\gamma}\right) \\
& \geq|Q(x)|\left(2^{s(s+1) r}\left(1-\frac{1}{4 m+1}\right)\right)^{m} \\
& \geq \frac{1}{2}|Q(x)| \cdot 2^{s(s+1) r m} \\
& \geq \frac{1}{4} \cdot 2^{s(s+1) r m} \quad \text { (Lemma 19) }
\end{aligned}
$$

where we used that $\left(1-\frac{1}{4 m+1}\right)^{m} \geq e^{-\frac{1}{4}} \geq 1 / 2$.
To prove part 3 of Lemma 16 note that $\operatorname{deg}\left(P_{s}\right)=2 s+1$. Thus, $\operatorname{deg}\left(A_{s, r}\right)$ and $\operatorname{deg}\left(B_{s, r}\right)$ are at most $(2 s+1) r$. Therefore, $\operatorname{deg}(p) \leq(2 s+1) r m$.

It remains to prove part 4 of Lemma 16. For any $i \in\{0,1,2, \ldots, s\}$ and any $v \in \mathbb{R}^{d}$ such that $\|v\| \leq 1$ define multivariate polynomials

$$
\begin{aligned}
f_{i, v}(x) & =\frac{\langle v, x\rangle}{\gamma}-2^{i} \\
q_{v}(x) & =P_{s}\left(\frac{\langle v, x\rangle}{\gamma}\right) \\
a_{v}(x) & =A_{s, r}\left(\frac{\langle v, x\rangle}{\gamma}\right) \\
b_{v}(x) & =B_{s, r}\left(\frac{\langle v, x\rangle}{\gamma}\right)
\end{aligned}
$$

Note that

$$
p(x)=\left[\sum_{i=1}^{m} a_{v_{i}}(x) \prod_{\substack{j: 1 \leq j \leq m \\ j \neq i}} b_{v_{j}}(x)\right]-\left(m-\frac{1}{2}\right) \prod_{j=1}^{n} b_{v_{j}}(x) .
$$

We bound the norms of these polynomials. We have

$$
\left\|f_{i, v}\right\|^{2}=\|v\|^{2} / \gamma^{2}+2^{2 i} \leq 2 \cdot 2^{2 s}
$$

where we used that $1 / \gamma \leq 2^{s}$ and $\|v\| \leq 1$. Since $q_{v}(x)=f_{i, v}\left(\frac{\langle v, x\rangle}{\gamma}\right) \prod_{i=1}^{s}\left(f_{i, v}\left(\frac{\langle v, x\rangle}{\gamma}\right)\right)^{2}$, using part 1 of Lemma 14 we upper bound the norm of $q_{v}$ as

$$
\begin{aligned}
\left\|q_{v}\right\|^{2} & \leq(2 s+1)^{2 s+1}\left\|f_{0, v}\right\|^{2} \prod_{i=1}^{s}\left\|f_{i, v}\right\|^{4} \\
& \leq(2 s+1)^{2 s+1}\left(2 \cdot 2^{2 s}\right)^{2 s+1}
\end{aligned}
$$

Using parts 3 and 2 of Lemma 14 we upper bound the norm of $a_{v}$ as

$$
\begin{aligned}
\left\|a_{v}\right\|^{2} & \leq 2\left\|\left(q_{v}\right)^{r}\right\|^{2}+2\left\|\left(q_{-v}\right)^{r}\right\|^{2} \\
& \left.\leq 2 r^{r(2 s+1)}\left(\left\|q_{v}\right\|^{2}\right)^{r}+2 r^{r(2 s+1)}\left\|q_{-v}\right\|^{2}\right)^{r} \\
& \leq 4 r^{r(2 s+1)}\left((2 s+1)^{2 s+1}\left(2 \cdot 2^{s}\right)^{2 s+1}\right)^{r} \\
& =4\left(2^{2 s} r(4 s+2)\right)^{(2 s+1) r}
\end{aligned}
$$

The same upper bound holds for $\left\|b_{v}\right\|^{2}$. Finally,

$$
\begin{aligned}
\|p\| \leq & {\left[\sum_{i=1}^{m}\left\|a_{v_{i}} \prod_{\substack{j: 1 \leq j \leq m \\
j \neq i}} b_{v_{j}}\right\|\right]+\left(m-\frac{1}{2}\right)\left\|\prod_{j=1}^{m} b_{v_{j}}\right\| } \\
\leq & {\left[\sum_{i=1}^{m} m^{(s+1 / 2) r m}\left\|a_{v_{i}}\right\| \prod_{\substack{j: 1 \leq j \leq m \\
j \neq i}}\left\|b_{v_{j}}\right\|\right] } \\
& +\left(m-\frac{1}{2}\right) m^{(s+1 / 2) r m} \prod_{j=1}^{m}\left\|b_{v_{j}}\right\| \\
\leq & (2 m-1 / 2) m^{(s+1 / 2) r m}\left(4\left(2^{2 s} r(4 s+2)\right)^{(2 s+1) r}\right)^{m / 2} \\
= & (2 m-1 / 2) 2^{m} \cdot\left(2^{2 s} r m(4 s+2)\right)^{(s+1 / 2) r m} .
\end{aligned}
$$

## E Proof of Theorem 5

Proof of Theorem 5. Since the examples $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right)$ are weakly linearly separable with margin $\gamma$,, there are vectors $w_{1}, w_{2}, \ldots, w_{K}$ satisfying (1) and (2).

Fix any $i \in\{1,2, \ldots, K\}$. Consider the $K-1$ vectors $\left(w_{i}-w_{j}\right) / 2$ for $j \in\{1,2, \ldots, K\} \backslash\{i\}$. Note that the vectors have norm at most 1 . We consider two cases regarding the relationship between $\gamma_{1}$ and $\gamma_{2}$.

Case 1: $\gamma_{1} \geq \gamma_{2}$. In this case, Theorem 7 implies that there exist a multivariate polynomial $p_{i}: \mathbb{R}^{d} \rightarrow \mathbb{R}$,

$$
\operatorname{deg}\left(p_{i}\right)=\left\lceil\log _{2}(2 K-2)\right\rceil \cdot\left\lceil\sqrt{\frac{2}{\gamma}}\right\rceil
$$

such that all examples $x$ in $R_{i}^{+}$(resp. $R_{i}^{-}$) satisfy $p_{i}(x) \geq 1 / 2$ (resp. $p_{i}(x) \leq-1 / 2$ ). Therefore, for all $t=$ $1,2, \ldots, T$, if $y_{t}=i$ then $p_{i}\left(x_{t}\right) \geq 1 / 2$, and if $y_{t} \neq i$ then $p_{i}\left(x_{t}\right) \leq-1 / 2$, and

$$
\left\|p_{i}\right\| \leq\left(188\left\lceil\log _{2}(2 K-2)\right\rceil \cdot\left\lceil\sqrt{\frac{2}{\gamma}}\right\rceil\right)^{\frac{1}{2}\left\lceil\log _{2}(2 K-2)\right\rceil \cdot\left\lceil\sqrt{\frac{2}{\gamma}}\right\rceil}
$$

By Lemma 9 , there exists $c_{i} \in \ell_{2}$ such that $\left\langle c_{i}, \phi(x)\right\rangle=p_{i}(x)$, and

$$
\left\|c_{i}\right\|_{\ell_{2}} \leq\left(376\left\lceil\log _{2}(2 K-2)\right\rceil \cdot\left\lceil\sqrt{\frac{2}{\gamma}}\right\rceil\right)^{\frac{1}{2}\left\lceil\log _{2}(2 K-2)\right\rceil \cdot\left\lceil\sqrt{\frac{2}{\gamma}}\right\rceil}
$$

Define vectors $u_{i} \in \ell_{2}$ as

$$
u_{i}=\frac{1}{\sqrt{K}} \cdot \frac{c_{i}}{\left(376\left\lceil\log _{2}(2 K-2)\right\rceil \cdot\left\lceil\sqrt{\frac{2}{\gamma}}\right\rceil\right)^{\frac{1}{2}\left\lceil\log _{2}(2 K-2)\right\rceil \cdot\left\lceil\sqrt{\frac{2}{\gamma}}\right\rceil}}
$$

Then, $\left\|u_{1}\right\|^{2}+\left\|u_{2}\right\|^{2}+\cdots+\left\|u_{K}\right\|^{2} \leq 1$. Furthermore, for all $t=1,2, \ldots, T,\left\langle u_{y_{t}}, \phi\left(x_{t}\right)\right\rangle \geq \gamma_{1}$ and for all $j \in\{1,2, \ldots, K\} \backslash\left\{y_{t}\right\},\left\langle u_{j}, \phi\left(x_{t}\right)\right\rangle \leq-\gamma_{1}$. In other words, $\left(\phi\left(x_{1}\right), y_{1}\right),\left(\phi\left(x_{2}\right), y_{2}\right), \ldots,\left(\phi\left(x_{T}\right), y_{T}\right)$ are strongly linearly separable with margin $\gamma_{1}=\max \left\{\gamma_{1}, \gamma_{2}\right\}$.

Case 2: $\gamma_{1}<\gamma_{2}$. In this case, Theorem 8 implies that there exist a multivariate polynomial $q_{i}: \mathbb{R}^{d} \rightarrow \mathbb{R}$,

$$
\operatorname{deg}\left(q_{i}\right)=(2 s+1) r(K-1),
$$

such that all examples $x$ in $R_{i}^{+}$(resp. $R_{i}^{-}$) satisfy $q_{i}(x) \geq 1 / 2$ (resp. $q_{i}(x) \leq-1 / 2$ ), and

$$
\left\|q_{i}\right\| \leq(4 K-5) 2^{K-1} \cdot\left(2^{s} r(K-1)(4 s+2)\right)^{(s+1 / 2) r(K-1)}
$$

Recall that here,

$$
r=2\left\lceil\frac{1}{4} \log _{2}(4 K-3)\right\rceil+1 \quad \text { and } \quad s=\left\lceil\log _{2}(1 / \gamma)\right\rceil
$$

Therefore, for all $t=1,2, \ldots, T$, if $y_{t}=i$ then $q_{i}\left(x_{t}\right) \geq 1 / 2$, and if $y_{t} \neq i$ then $q_{i}\left(x_{t}\right) \leq-1 / 2$.
By Lemma 9, there exists $c_{i}^{\prime} \in \ell_{2}$ such that $\left\langle c_{i}^{\prime}, \phi(x)\right\rangle=p_{i}(x)$, and

$$
\left\|c_{i}^{\prime}\right\|_{\ell_{2}} \leq(4 K-5) 2^{K-1} \cdot\left(2^{s+1} r(K-1)(4 s+2)\right)^{(s+1 / 2) r(K-1)}
$$

Define vectors $u_{i}^{\prime} \in \ell_{2}$ as

$$
u_{i}^{\prime}=\frac{c_{i}^{\prime} \cdot\left(2^{s+1} r(K-1)(4 s+2)\right)^{-(s+1 / 2) r(K-1)}}{\sqrt{K}(4 K-5) 2^{K-1}}
$$

Then, $\left\|u_{1}^{\prime}\right\|^{2}+\left\|u_{2}^{\prime}\right\|^{2}+\cdots+\left\|u_{K}^{\prime}\right\|^{2} \leq 1$. Furthermore, for all $t=1,2, \ldots, T,\left\langle u_{y_{t}}^{\prime}, \phi\left(x_{t}\right)\right\rangle \geq \gamma_{2}$ and for all $j \in\{1,2, \ldots, K\} \backslash\left\{y_{t}\right\},\left\langle u_{j}^{\prime}, \phi\left(x_{t}\right)\right\rangle \leq-\gamma_{2}$. In other words, $\left(\phi\left(x_{1}\right), y_{1}\right),\left(\phi\left(x_{2}\right), y_{2}\right), \ldots,\left(\phi\left(x_{T}\right), y_{T}\right)$ are strongly linearly separable with margin $\gamma_{2}=\max \left\{\gamma_{1}, \gamma_{2}\right\}$.

In summary, the examples are strongly linearly separable with $\operatorname{margin} \gamma^{\prime}=\max \left\{\gamma_{1}, \gamma_{2}\right\}$. Finally, observe that for any $t=1,2, \ldots, T$,

$$
k\left(x_{t}, x_{t}\right)=\frac{1}{1-\frac{1}{2}\left\|x_{t}\right\|^{2}} \leq 2
$$

## F Supplementary Materials for Section 6

We plot in Figures 6, 7, 8 the final decision boundaries learned by each algorithm in the two datasets (Figures 4 and 5), i.e. its decision boundaries output at the end of round $T=5 \times 10^{6}$.

## G Nearest neighbor algorithm

```
Algorithm 4 Nearest-Neighbor Algorithm
Require: Number of classes \(K\), number of rounds \(T\).
Require: Inner product space \((V,\langle\cdot, \cdot\rangle)\).
Initialize \(S \leftarrow \emptyset\)
for \(t=1,2, \ldots, T\) : do
    if \(\min _{(x, y) \in S}\left\|x_{t}-x\right\| \leq \gamma\) then
            Find nearest neighbor
            \((\widetilde{x}, \widetilde{y})=\operatorname{argmin}_{(x, y) \in S}\left\|x_{t}-x\right\|\)
            Predict \(\widehat{y}_{t}=\widetilde{y}\)
    else
            Predict \(\widehat{y}_{t} \sim \operatorname{Uniform}(\{1,2, \ldots, K\})\)
            Receive feedback \(z_{t}=\mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\)
            if \(z_{t}=0\) then
                \(S \leftarrow S \cup\left\{\left(x_{t}, \widehat{y}_{t}\right)\right\}\)
```

In this section we analyze Nearest-Neighbor Algorithm shown as Algorithm 4. The algorithm is based on the obvious idea that, under the weak linear separability assumption, two examples that are close to each other must have the same label. The lemma below formalizes this intuition.

Lemma 20 (Non-separation lemma). Let $(V,\langle\cdot, \cdot\rangle)$ be a vector space, $K$ be a positive integer and let $\gamma$ be a positive real number. Suppose $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right) \in V \times\{1,2, \ldots, K\}$ are labeled examples that are weakly linearly separable with margin $\gamma$. For $i, j$ in $\{1,2, \ldots, T\}$, $i f\left\|x_{i}-x_{j}\right\|_{2} \leq \gamma$ then $y_{i}=y_{j}$.

Proof. Suppose for the sake on contradiction that $y_{i} \neq y_{j}$. By Definition 1, there exists vectors $w_{1}, \ldots, w_{K}$ such that conditions (1) and (2) are satisfied.

Specifically,

$$
\begin{aligned}
& \left\langle w_{y_{i}}-w_{y_{j}}, x_{i}\right\rangle \geq \gamma \\
& \left\langle w_{y_{j}}-w_{y_{i}}, x_{j}\right\rangle \geq \gamma .
\end{aligned}
$$

This implies that

$$
\left\langle w_{y_{i}}-w_{y_{j}}, x_{i}-x_{j}\right\rangle \geq 2 \gamma
$$

On the other hand,

$$
\left\langle w_{y_{i}}-w_{y_{j}}, x_{i}-x_{j}\right\rangle \leq\left\|w_{y_{i}}-w_{y_{j}}\right\| \cdot\left\|x_{i}-x_{j}\right\| \leq \sqrt{2} \gamma
$$

where the first inequality is from Cauchy-Schwartz inequality, the second inequality is from that $\left\|w_{y_{i}}-w_{y_{j}}\right\| \leq$ $\sqrt{2\left(\left\|w_{y_{i}}\right\|^{2}+\left\|w_{y_{j}}\right\|^{2}\right)} \leq \sqrt{2}$ and our assumption on $x_{i}$ and $x_{j}$. Therefore, we reach a contradiction.

We also need to define several notions. A subset $S \subseteq \mathbb{R}^{d}$ is called a $\gamma$-packing if for any $x, x^{\prime} \in S$ such that $x \neq x^{\prime}$ we have $\left\|x-x^{\prime}\right\|>\gamma$. The following lemma is standard. Also recall that $\mathrm{B}(x, R)=\left\{x^{\prime} \in \mathbb{R}^{d}:\left\|x^{\prime}-x\right\| \leq R\right\}$ denotes the closed ball of radius $R$ centered a point $x$. For set $S \subseteq \mathbb{R}^{d}$, denote by $\operatorname{Vol}(S)$ the volume of $S$.

Lemma 21 (Size of $\gamma$-packing). Let $\gamma$ and $R$ be positive real numbers. If $S \subseteq \mathrm{~B}(\mathbf{0}, R) \subseteq \mathbb{R}^{d}$ is a $\gamma$-packing then

$$
|S| \leq\left(\frac{2 R}{\gamma}+1\right)^{d}
$$

Proof. If $S$ is a $\gamma$-packing then $\{\mathrm{B}(x, \gamma / 2): x \in S\}$ is a collection of disjoint balls of radius $\gamma$ that fit into $\mathrm{B}(\mathbf{0}, R+\gamma / 2)$. Thus,

$$
|S| \cdot \operatorname{Vol}(\mathrm{B}(\mathbf{0}, \gamma / 2)) \leq \operatorname{Vol}(\mathrm{B}(\mathbf{0}, R+\gamma / 2))
$$

Hence,

$$
|S| \leq \frac{\operatorname{Vol}(\mathrm{B}(\mathbf{0}, R+\gamma / 2))}{\operatorname{Vol}(\mathrm{B}(\mathbf{0}, \gamma / 2))}=\left(\frac{R+\gamma / 2}{\gamma / 2}\right)^{d}=\left(\frac{2 R}{\gamma}+1\right)^{d}
$$

Theorem 22 (Mistake upper bound for Nearest-Neighbor Algorithm). Let $K$ and $d$ be positive integers and let $\gamma, R$ be a positive real numbers. Suppose $\left(x_{1}, y_{1}\right), \ldots,\left(x_{T}, y_{T}\right) \in \mathbb{R}^{d} \times\{1,2, \ldots, K\}$ are labeled examples that are weakly linearly separable with margin $\gamma$ and satisfy $\left\|x_{1}\right\|,\left\|x_{2}\right\|, \ldots,\left\|x_{T}\right\| \leq R$. Then, the expected number of mistakes made by Algorithm 4 is at most

$$
(K-1)\left(\frac{2 R}{\gamma}+1\right)^{d}
$$

Proof. Let $M$ be the number of mistakes made by the algorithm. Let $b_{t}$ be the indicator that line 7 is executed at time step $t$, i.e. we fall into the "else" case. Note that if $b_{t}=0$, then by Lemma 20, the prediction $\widehat{y}_{t}$ must equal $y_{t}$, i.e. $z_{t}=0$. Therefore, $M=\sum_{t=1}^{T} z_{t}=\sum_{t=1}^{T} b_{t} z_{t}$. Let $U=\sum_{t=1}^{T} b_{t}\left(1-z_{t}\right)$. Clearly, $|S|=U$. Since $S \subseteq \mathrm{~B}(\mathbf{0}, R)$ is a $\gamma$-packing, $U=|S| \leq\left(\frac{2 R}{\gamma}+1\right)^{d}$.

Note that when $b_{t}=1, \widehat{y}_{t}$ is chosen uniformly at random, we have

$$
\mathbf{E}\left[z_{t} \mid b_{t}=1\right]=\frac{K-1}{K}
$$

Therefore,

$$
\mathbf{E}[M]=\mathbf{E}\left[\sum_{t=1}^{T} b_{t} z_{t}\right]=\frac{K-1}{K} \mathbf{E}\left[\sum_{t=1}^{T} b_{t}\right]
$$

On the other hand,

$$
\mathbf{E}[U]=\mathbf{E}\left[\sum_{t=1}^{T} b_{t}\left(1-z_{t}\right)\right]=\frac{1}{K} \mathbf{E}\left[\sum_{t=1}^{T} b_{t}\right]
$$

Therefore,

$$
\mathbf{E}[M]=(K-1) \mathbf{E}[U] \leq(K-1)\left(\frac{2 R}{\gamma}+1\right)^{d}
$$

## H NP-hardness of the weak labeling problem

Any algorithm for the bandit setting collects information in the form of so called strongly labeled and weakly labeled examples. Strongly-labeled examples are those for which we know the class label. Weakly labeled example is an example for which we know that class label can be anything except for a particular one class.

A natural strategy for each round is to find vectors $w_{1}, w_{2}, \ldots, w_{K}$ that linearly separate the examples seen in the previous rounds and use the vectors to predict the label in the next round. More precisely, we want to find both the vectors $w_{1}, w_{2}, \ldots, w_{K}$ and label for each example consistent with its weak and/or strong labels such that $w_{1}, w_{2}, \ldots, w_{K}$ linearly separate the labeled examples. We show this problem is NP-hard even for $K=3$.

Clearly, the problem is at least as hard as the decision version of the problem where the goal is to determine if such vectors and labeling exist. We show that this problem is NP-complete.

We use symbols $1,2, \ldots, K$ for strong labels and symbols $\overline{1}, \overline{2}, \ldots, \bar{K}$ for weak labels. Formally, the weak labeling problem can be described as below:

## Weak Labeling

Given: Feature-label pairs $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right)$ in $\{0,1\}^{d} \times\{1,2, \ldots, K, \overline{1}, \overline{2}, \ldots, \bar{K}\}$.
Question: Do there exist $w_{1}, w_{2}, \ldots, w_{K} \in \mathbb{R}^{d}$ such that for all $t=1,2, \ldots, T$,

$$
\begin{aligned}
& y_{t} \in\{1,2, \ldots, K\} \Longrightarrow \forall i \in\{1,2, \ldots, K\} \backslash\left\{y_{t}\right\} \quad\left\langle w_{y_{t}}, x_{t}\right\rangle>\left\langle w_{i}, x_{t}\right\rangle \\
& \text { and } \\
& y_{t} \in\{\overline{1}, \overline{2}, \ldots, \bar{K}\} \Longrightarrow \exists i \in\{1,2, \ldots, K\} \quad\left\langle w_{i}, x_{t}\right\rangle>\left\langle w_{\overline{y_{t}}}, x_{t}\right\rangle \text { ? }
\end{aligned}
$$

The hardness proof is based on a reduction from the set splitting problem, which is proven to be NP-complete by Lovász Garey and Johnson [1979], to our weak labeling problem. The reduction is adapted from Blum and Rivest [1993].

## Set Splitting

Given: A finite set $S$ and a collection $C$ of subsets $c_{i}$ of $S$.
Question: Do there exist disjoint sets $S_{1}$ and $S_{2}$ such that $S_{1} \cup S_{2}=S$ and $\forall i, c_{i} \nsubseteq S_{1}$ and $c_{i} \nsubseteq S_{2}$ ?

Below we show the reduction. Suppose we are given an instance of the set splitting problem

$$
S=\{1,2, \ldots, N\}, C=\left\{c_{1}, c_{2}, \ldots, c_{M}\right\} .
$$

We create the weak labeling instance as follows. Let $d=N+1$ and $K=3$. Define $\mathbf{0}$ as the zero vector $(0, \ldots, 0) \in \mathbb{R}^{N}$ and $\mathbf{e}_{i}$ as the $i$-th standard vector $\left.(0, \ldots, 1, \ldots, 0) \in \mathbb{R}^{N}\right)$. Then we include all the following feature-label pairs:

- Type $1:(x, y)=((\mathbf{0}, 1), 3)$,
- Type 2: $(x, y)=\left(\left(\mathbf{e}_{i}, 1\right), \overline{3}\right)$ for all $i \in\{1,2, \ldots, N\}$,
- Type 3: $(x, y)=\left(\left(\sum_{i \in c_{j}} \mathbf{e}_{i}, 1\right), 3\right)$ for all $j \in\{1,2, \ldots, M\}$.

For example, if we have $S=\{1,2,3\}, C=\left\{c_{1}, c_{2}\right\}, c_{1}=\{1,2\}, c_{2}=\{2,3\}$, then we create the weak labeling sample set as:

$$
\{((0,0,0,1), 3),((1,0,0,1), \overline{3}),((0,1,0,1), \overline{3}),((0,0,1,1), \overline{3}),((1,1,0,1), 3),((0,1,1,1), 3)\} .
$$

The following lemma shows that answering this weak labeling problem is equivalent to answering the original set splitting problem.

Lemma 23. Any instance of the set splitting problem is a YES instance if and only if the corresponding instance of the weak labeling problem (as described above) is a YES instance.
Proof. $(\Longrightarrow)$ Let $S_{1}, S_{2}$ be the solution of the set splitting problem. Define

$$
w_{1}=\left(a_{1}, a_{2}, \cdots, a_{N},-\frac{1}{2}\right),
$$

where for all $i \in\{1,2, \ldots, N\}, a_{i}=1$ if $i \in S_{1}$ and $a_{i}=-N$ if $i \notin S_{1}$. Similarly, define

$$
w_{2}=\left(b_{1}, b_{2}, \cdots, b_{N},-\frac{1}{2}\right)
$$

where for all $i \in\{1,2, \ldots, N\}, b_{i}=1$ if $i \in S_{2}$ and $b_{i}=-N$ if $i \notin S_{2}$. Finally, define

$$
w_{3}=(0,0, \cdots, 0)
$$

the zero vector. To see this is a solution for the weak labeling problem, we verify separately for Type 1-3 samples defined above. For Type 1 sample, we have

$$
\left\langle w_{3}, x\right\rangle=0>-\frac{1}{2}=\left\langle w_{1}, x\right\rangle=\left\langle w_{2}, x\right\rangle .
$$

For a Type 2 sample that corresponds to index $i$, we have either $i \in S_{1}$ or $i \in S_{2}$ because $S_{1} \cup S_{2}=\{1,2, \ldots, N\}$ is guaranteed. Thus, either $a_{i}=1$ or $b_{i}=1$. If $a_{i}=1$ is the case, then

$$
\left\langle w_{1}, x\right\rangle=a_{i}-\frac{1}{2}=\frac{1}{2}>0=\left\langle w_{3}, x\right\rangle
$$

similarly if $b_{i}=1$, we have $\left\langle w_{2}, x\right\rangle>\left\langle w_{3}, x\right\rangle$.
For a Type 3 sample that corresponds to index $j$, Since $c_{j} \not \subset S_{1}$, there exists some $i^{\prime} \in c_{j}$ and $i^{\prime} \notin S_{1}$. Thus we have $x_{i^{\prime}}=1, a_{i^{\prime}}=-N$, and therefore

$$
\begin{aligned}
\left\langle w_{1}, x\right\rangle & =a_{i^{\prime}} x_{i^{\prime}}+\sum_{i \in\{1,2, \ldots, N\} \backslash\left\{i^{\prime}\right\}} a_{i} x_{i}-\frac{1}{2} \\
& \leq-N+(N-1)-\frac{1}{2}<0=\left\langle w_{3}, x\right\rangle
\end{aligned}
$$

Because $c_{j} \not \subset S_{2}$ also holds, we also have $\left\langle w_{2}, x\right\rangle<\left\langle w_{3}, x\right\rangle$. This direction is therefore proved.
$(\Longleftarrow)$ Given the solution $w_{1}, w_{2}, w_{3}$ of the weak labeling problem, we define

$$
\begin{aligned}
& S_{1}=\left\{i \in\{1,2, \ldots, n\}:\left\langle w_{1}-w_{3},\left(\mathbf{e}_{i}, 1\right)\right\rangle>0\right\} \\
& S_{2}=\left\{i \in\{1,2, \ldots, n\}:\left\langle w_{2}-w_{3},\left(\mathbf{e}_{i}, 1\right)\right\rangle>0 \text { and } i \notin S_{1}\right\} .
\end{aligned}
$$

It is not hard to see $S_{1} \cap S_{2}=\emptyset$ and $S_{1} \cup S_{2}=\{1,2, \ldots, N\}$. The former is because $S_{2}$ only includes elements that are not in $S_{1}$. For the latter, note that $\left(\mathbf{e}_{i}, 1\right)$ is the feature vector for Type 2 samples. Because Type 2 samples all have
label $\overline{3}$, for any $i \in\{1,2, \ldots, N\}$, one of the following must hold: $\left\langle w_{1}-w_{3},\left(\mathbf{e}_{i}, 1\right)\right\rangle>0$ or $\left\langle w_{2}-w_{3},\left(\mathbf{e}_{i}, 1\right)\right\rangle>0$. This implies $i \in S_{1}$ or $i \in S_{2}$.

Now we show $\forall j, c_{j} \not \subset S_{1}$ and $c_{j} \not \subset S_{2}$ by contradiction. Assume there exists some $j$ such that $c_{j} \subset S_{1}$. By our definition of $S_{1}$, we have $\left\langle w_{1}-w_{3},\left(\mathbf{e}_{i}, 1\right)\right\rangle>0$ for all $i \in c_{j}$. Therefore,

$$
\sum_{i \in c_{j}}\left\langle w_{1}-w_{3},\left(\mathbf{e}_{i}, 1\right)\right\rangle=\left\langle w_{1}-w_{3},\left(\sum_{i \in c_{j}} \mathbf{e}_{i},\left|c_{j}\right|\right)\right\rangle>0 .
$$

Because Type 1 sample has label 3, we also have

$$
\left\langle w_{1}-w_{3},(\mathbf{0}, 1)\right\rangle<0 .
$$

Combining the above two inequalities, we get

$$
\left\langle w_{1}-w_{3},\left(\sum_{i \in c_{j}} \mathbf{e}_{i}, 1\right)\right\rangle=\left\langle w_{1}-w_{3},\left(\sum_{i \in c_{j}} \mathbf{e}_{i},\left|c_{j}\right|\right)\right\rangle-\left(\left|c_{j}\right|-1\right)\left\langle w_{1}-w_{3},(\mathbf{0}, 1)\right\rangle>0 .
$$

Note that $\left(\sum_{i \in c_{j}} \mathbf{e}_{i}, 1\right)$ is a feature vector for Type 3 samples. Thus the above inequality contradicts that Type 3 samples have label 3 . Therefore, $c_{j} \not \subset S_{1}$. If we assume there exists some $c_{j} \subset S_{2}$, same arguments apply and also lead to contradiction.

## I Mistake lower bound for ignorant algorithms

In this section, we prove a mistake lower bound for a family of algorithms called ignorant algorithms. Ignorant algorithms ignore the examples on which they make mistakes. This assumption seems strong, but as we will explain below, it is actually natural, and several recently proposed bandit linear classification algorithms that achieve $\sqrt{T}$ regret bounds belong to this family, e.g., SOBA [Beygelzimer et al., 2017], OBAMA [Foster et al., 2018]. Also, Nearest-Neighbor Algorithm (Algorithm 4) presented in Appendix G is an ignorant algorithm.

Under the assumption that the examples lie in in the unit ball of $\mathbb{R}^{d}$ and are weakly linearly separable with margin $\gamma$, we show that any ignorant algorithm must make at least $\Omega\left(\left(\frac{1}{160 \gamma}\right)^{(d-2) / 4}\right)$ mistakes in the worst case. In other words, an algorithm that achieves a better mistake bound cannot ignore examples on which it makes a mistake and it must make a meaningful update on such examples.

To formally define ignorant algorithms, we define the conditional distribution from which an algorithm draws its predictions. Formally, given an algorithm $\mathcal{A}$ and an adversarial strategy, we define

$$
p_{t}(y \mid x)=\operatorname{Pr}\left[y_{t}=y \mid\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right) \ldots,\left(x_{t-1}, y_{t-1}\right), x_{t}=x\right] .
$$

In other words, in any round $t$, conditioned on the past $t-1$ rounds, the algorithm $\mathcal{A}$ chooses $y_{t}$ from probability distribution $p_{t}\left(\cdot \mid x_{t}\right)$. Formally, $p_{t}$ is a function $p:\{1,2, \ldots, K\} \times \mathbb{R}^{d} \rightarrow[0,1]$ such that $\sum_{y=1}^{K} p_{t}(y \mid x)=1$ for any $x \in \mathbb{R}^{d}$.

Definition 24 (Ignorant algorithm). An algorithm $\mathcal{A}$ for Online Multiclass Linear Classification with BANDIT FEEDBACK is called ignorant iffor every $t=1,2, \ldots, T, p_{t}$ is determined solely by the sequence $\left(x_{a_{1}}, y_{a_{1}}\right),\left(x_{a_{2}}, y_{a_{2}}\right)$, $\ldots,\left(x_{a_{n}}, y_{a_{n}}\right)$ of labeled examples from the rounds $1 \leq a_{1}<a_{2}<\cdots<a_{n}<t$ in which the algorithm makes a correct prediction.

An equivalent definition of an ignorant algorithm is that the memory state of the algorithm does not change after it makes a mistake. Equivalently, the memory state of an ignorant algorithm is completely determined by the sequence of labeled examples on which it made correct prediction.

To explain the definition, consider an ignorant algorithm $\mathcal{A}$. Suppose that on a sequence of examples $\left(x_{1}, y_{1}\right)$, $\left(x_{2}, y_{2}\right), \ldots,\left(x_{t-1}, y_{t-1}\right)$ generated by some adversary the algorthm $\mathcal{A}$ makes correct predictions in rounds $a_{1}, a_{2}, \ldots, a_{n}$ where $1 \leq a_{1}<a_{2}<\cdots<a_{n}<t$ and errors on rounds $\{1,2, \ldots, t-1\} \backslash\left\{a_{1}, a_{2}, \ldots, a_{n}\right\}$. Suppose that on another sequence of examples $\left(x_{1}^{\prime}, y_{1}^{\prime}\right),\left(x_{2}^{\prime}, y_{2}^{\prime}\right), \ldots,\left(x_{s-1}^{\prime}, y_{s-1}^{\prime}\right)$ generated by another adversary the algorithm $\mathcal{A}$ makes correct predictions in rounds $b_{1}, b_{2}, \ldots, b_{n}$ where $1 \leq b_{1}<b_{2}<\cdots<b_{n}<s$ and errors on rounds $\{1,2, \ldots, s-1\} \backslash\left\{b_{1}, b_{2}, \ldots, b_{n}\right\}$. Futhermore, suppose

$$
\begin{aligned}
\left(x_{a_{1}}, y_{a_{1}}\right) & =\left(x_{b_{1}}^{\prime}, y_{b_{1}}^{\prime}\right) \\
\left(x_{a_{2}}, y_{a_{2}}\right) & =\left(x_{b_{2}}^{\prime}, y_{b_{2}}^{\prime}\right) \\
\vdots & \\
\left(x_{a_{n}}, y_{a_{n}}\right) & =\left(x_{b_{2}}^{\prime}, y_{b_{n}}^{\prime}\right) .
\end{aligned}
$$

Then, as $\mathcal{A}$ is ignorant,

$$
\operatorname{Pr}\left[y_{t}=y \mid\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right) \ldots,\left(x_{t-1}, y_{t-1}\right), x_{t}=x\right]=\operatorname{Pr}\left[y_{t}^{\prime}=y \mid\left(x_{1}^{\prime}, y_{1}^{\prime}\right),\left(x_{2}^{\prime}, y_{2}^{\prime}\right) \ldots,\left(x_{t-1}^{\prime}, y_{t-1}^{\prime}\right), x_{t}^{\prime}=x\right] .
$$

Note that the sequences $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{t-1}, y_{t-1}\right)$ and $\left(x_{1}^{\prime}, y_{1}^{\prime}\right),\left(x_{2}^{\prime}, y_{2}^{\prime}\right), \ldots,\left(x_{s-1}^{\prime}, y_{s-1}^{\prime}\right)$ might have different lengths and and $\mathcal{A}$ might error in different sets of rounds. As a special case, if an ignorant algorithm makes a mistake in round $t$ then $p_{t+1}=p_{t}$.

Our main result is the following lower bound on the expected number of mistakes for ignorant algorithms.
Theorem 25 (Mistake lower bound for ignorant algorithms). Let $\gamma \in(0,1)$ and let d be a positive integer. Suppose $\mathcal{A}$ is an ignorant algorithm for Online Multiclass Linear Classification with Bandit Feedback. There exists $T$ and an adversary that sequentially chooses labeled examples $\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{T}, y_{T}\right) \in \mathbb{R}^{d} \times\{1,2\}$ such that the examples are strongly linearly separable with magin $\gamma$ and $\left\|x_{1}\right\|,\left\|x_{2}\right\|, \ldots,\left\|x_{T}\right\| \leq 1$, and the expected number of mistakes made by $\mathcal{A}$ is at least

$$
\frac{1}{10}\left(\frac{1}{160 \gamma}\right)^{\frac{d-2}{4}}
$$

Before proving the theorem, we need the following lemma.
Lemma 26. Let $\gamma \in\left(0, \frac{1}{160}\right)$, let $d$ be a positive integer and let $N=\left(\frac{1}{2 \sqrt{40 \gamma}}\right)^{d-2}$. There exist vectors $u_{1}, u_{2}, \ldots, u_{N}$, $v_{1}, v_{2}, \ldots, v_{N}$ in $\mathbb{R}^{d}$ such that for all $i, j \in\{1,2, \ldots, N\}$,

$$
\begin{aligned}
\left\|u_{i}\right\| & \leq 1 \\
\left\|v_{j}\right\| & \leq 1, \\
\left\langle u_{i}, v_{j}\right\rangle & \geq \gamma, \quad \text { if } i=j \\
\left\langle u_{i}, v_{j}\right\rangle & \leq-\gamma, \quad \text { if } i \neq j
\end{aligned}
$$

Proof. By Lemma 6 of Long [1995], there exists vectors $z_{1}, z_{2}, \ldots, z_{N} \in \mathbb{R}^{d-1}$ such that $\left\|z_{1}\right\|=\left\|z_{2}\right\|=\cdots=$ $\left\|z_{N}\right\|=1$ and the angle between the vectors is $\measuredangle\left(z_{i}, z_{j}\right) \geq \sqrt{40 \gamma}$ for $i \neq j, i, j \in\{1,2, \ldots, N\}$. Since $\cos \theta \leq$ $1-\theta^{2} / 5$ for any $\theta \in[-\pi, \pi]$, this implies that

$$
\begin{aligned}
& \left\langle z_{i}, z_{j}\right\rangle=1, \quad \text { if } i=j \\
& \left\langle z_{i}, z_{j}\right\rangle \leq 1-8 \gamma, \quad \text { if } i \neq j
\end{aligned}
$$

Define $v_{i}=\left(\frac{1}{2} z_{i}, \frac{1}{2}\right)$, and $u_{i}=\left(\frac{1}{2} z_{i},-\frac{1}{2}(1-4 \gamma)\right)$ for all $i \in\{1,2, \ldots, N\}$. It can be easily checked that for all $i,\left\|v_{i}\right\| \leq 1$ and $\left\|u_{i}\right\| \leq 1$. Additionally,

$$
\left\langle u_{i}, v_{j}\right\rangle=\frac{1}{4}\left\langle z_{i}, z_{j}\right\rangle-\frac{1-4 \gamma}{4}
$$

Thus,

$$
\begin{aligned}
& \left\langle u_{i}, v_{j}\right\rangle \geq \gamma, \quad \text { if } i=j, \\
& \left\langle u_{i}, v_{j}\right\rangle \leq-\gamma, \quad \text { if } i \neq j
\end{aligned}
$$

Proof of Theorem 25. We consider the strategy for the adversary described in Algorithm 5.

```
Algorithm 5 ADVERSARY'S STRATEGY
Define \(T=N\) and \(v_{1}, v_{2}, \ldots, v_{N}\) as in Lemma 26.
Define \(q_{0}=\frac{1}{\sqrt{T}}\).
Initialize PHASE \(=1\).
for \(t=1,2, \ldots, T\) do
    if \(\operatorname{PHASE}=1\) then
        if \(p_{t}\left(1 \mid v_{t}\right)<1-q_{0}\) then
            \(\left(x_{t}, y_{t}\right) \leftarrow\left(v_{t}, 1\right)\)
        else
            \(\left(x_{t}, y_{t}\right) \leftarrow\left(v_{t}, 2\right)\)
            PHASE \(\leftarrow 2\)
    else
        \(\left(x_{t}, y_{t}\right) \leftarrow\left(x_{t-1}, y_{t-1}\right)\)
```

Let $\tau$ be the time step $t$ in which the adversary sets PHASE $\leftarrow 2$. If the adversary never sets PHASE $\leftarrow 2$, we define $\tau=T+1$. Then,

$$
\mathbf{E}\left[\sum_{t=1}^{T} \mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\right] \geq \mathbf{E}\left[\sum_{t=1}^{\tau-1} \mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\right]+\mathbf{E}\left[\sum_{t=\tau}^{T} \mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\right]
$$

We upper bound each of last two terms separately.
In rounds $1,2, \ldots, \tau-1$, the algorithm predicts the incorrect class 2 with probability at least $q_{0}$. Thus,

$$
\begin{equation*}
\mathbf{E}\left[\sum_{t=1}^{\tau-1} \mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\right]=q_{0} \mathbf{E}[(\tau-1)] \tag{18}
\end{equation*}
$$

In rounds $\tau, \tau+1, \ldots, T$, all the examples are the same and are equal to $\left(v_{\tau}, 2\right)$. Let $s$ be the first time step $t$ such that $t \geq \tau$ and the algorithm makes a correct prediction. If the algorithm makes mistakes in all rounds $\tau, \tau+1, \ldots, T$, we define $s=T+1$. By definition the algorithm makes mistakes in rounds $\tau, \tau+1, \ldots, s-1$. Therefore,

$$
\begin{equation*}
\mathbf{E}\left[\sum_{t=\tau}^{T} \mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\right] \geq \mathbf{E}[s-\tau] . \tag{19}
\end{equation*}
$$

Since the algorithm is ignorant, conditioned on $\tau$ and $q \triangleq p_{\tau}\left(2 \mid v_{\tau}\right), s-\tau$ follows a truncated geometric distribution with parameter $q$ (i.e., $s-\tau$ is 0 with probability $q, 1$ with probability $(1-q) q, 2$ with probability $\left.(1-q)^{2} q, \ldots\right)$. Its conditional expectation can be calculated as follows:

$$
\begin{aligned}
\mathbf{E}[s-\tau \mid \tau, q] & =\sum_{i=1}^{T+1-\tau} i \times \operatorname{Pr}[s-\tau=i \mid \tau, q] \\
& =\sum_{j=1}^{T+1-\tau} \operatorname{Pr}[s-\tau \geq j \mid \tau, q]=\sum_{j=1}^{T+1-\tau}(1-q)^{j} \geq \sum_{j=1}^{T+1-\tau}\left(1-q_{0}\right)^{j}=\frac{1-q_{0}}{q_{0}}\left(1-\left(1-q_{0}\right)^{T-\tau+1}\right) .
\end{aligned}
$$

Therefore, by the tower property of conditional expectation,

$$
\mathbf{E}[s-\tau \mid \tau]=\mathbf{E}[\mathbf{E}[s-\tau \mid \tau, q] \mid \tau] \geq \frac{1-q_{0}}{q_{0}}\left(1-\left(1-q_{0}\right)^{T-\tau+1}\right)
$$

Combining this fact with Equations (18) and (19), we have that

$$
\begin{aligned}
\mathbf{E}\left[\sum_{t=1}^{T} \mathbb{1}\left[\widehat{y}_{t} \neq y_{t}\right]\right] & \geq q_{0} \mathbf{E}[\tau-1]+\mathbf{E}\left[\frac{1-q_{0}}{q_{0}}\left(1-\left(1-q_{0}\right)^{T-\tau+1}\right)\right] \\
& =\mathbf{E}\left[q_{0}(\tau-1)+\frac{1-q_{0}}{q_{0}}\left(1-\left(1-q_{0}\right)^{T-\tau+1}\right)\right]
\end{aligned}
$$

We lower bound the last expression by considering two cases for $\tau$. If $\tau \geq \frac{1}{2} T+1$, then the last expression is lower bounded by $\frac{1}{2} q_{0} T=\frac{1}{2} \sqrt{T}$. If $\tau<\frac{1}{2} T+1$, it is lower bounded by

$$
\begin{aligned}
& \frac{1-q_{0}}{q_{0}}\left(1-\left(1-q_{0}\right)^{\frac{1}{2} T}\right) \\
& =\frac{1-q_{0}}{q_{0}}\left(1-\left(1-q_{0}\right)^{\frac{1}{2 q_{0}^{2}}}\right) \\
& \geq \frac{1-\frac{1}{\sqrt{2}}}{q_{0}}\left(1-\frac{1}{\sqrt{e}}\right) \\
& \geq \frac{1}{10} \sqrt{T} .
\end{aligned}
$$

Observe that in phase 1 , the labels are equal to 1 and in phase 2 the labels are equal to 2 . Note that $\left(x_{\tau}, y_{\tau}\right)=$ $\left(x_{\tau+1}, y_{\tau+1}\right)=\cdots=\left(x_{T}, y_{T}\right)=\left(v_{\tau}, 2\right)$. Consider the vectors $u_{1}, u_{2}, \ldots, u_{N}$ as defined in Lemma 26. We claim that $w_{1}=-u_{\tau} / 2$ and $w_{2}=u_{\tau} / 2$ satisfy the conditions of strong linear separability.

Clearly $\left\|w_{1}\right\|^{2}+\left\|w_{2}\right\|^{2} \leq\left(\left\|w_{1}\right\|+\left\|w_{2}\right\|\right)^{2} \leq\left(\frac{1}{2}+\frac{1}{2}\right)^{2} \leq 1$. By Lemma 26, we have $\left\langle w_{2} / 2, x_{t}\right\rangle=\left\langle u_{\tau} / 2, v_{\tau}\right\rangle \geq$ $\gamma / 2, \forall t \geq \tau$ and $\left\langle w_{2} / 2, x_{t}\right\rangle=\left\langle u_{\tau} / 2, v_{t}\right\rangle \leq-\gamma / 2$ for all $t<\tau$. Similarly, $\left\langle w_{1} / 2, x_{t}\right\rangle \leq-\gamma / 2$ for all $t \geq \tau$ and $\left\langle w_{1} / 2, x_{t}\right\rangle \geq \gamma / 2$ for all $t<\tau$. Thus, the examples are strongly linearly separable with margin $\gamma$.
